THE CANADIAN ENGINEER

ESTABLISHED 1893

ISSUED WEEKLY IN THE INTERESTS OF THE CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Index to Volume 25

JULY—DECEMBER, 1913

27/7/14

THE CANADIAN ENGINEER

Head Office, 62 Church St., TORONTO

MONTREAL WINNIPEG

INDEX TO VOLUME 25

JULY to DECEMBER, 1913

NOTE.—Figures in page columns refer to the continuous paging of this volume, except in the department of the index devoted to "Contracts," in which the figure in the first column denotes the number of the issue in the volume (26 issues in all), and the second number denotes the page in that issue. As an example, "Addition to Factory, Vancouver.....6, 82," indicates page 82 of issue No. 6.

PLATE GIRDER BRIDGES IN RAILWAY CONSTRUCTION

PART II

CONSIDERATION OF SECTIONS OF MATERIAL—THE FRAMING OF THE VARIOUS SECTIONS—SHIPMENT AND ERECTION OF PLATE GIRDER SPANS—ADAPTABILITY OF DESIGN TO SHOP PRACTICE AND ERECTION CONDITIONS

By C. H. MARRS, C.E.

Erecting Engineer, Hamilton Bridge Works Company, Hamilton, Ont.

THE first part of this article, appearing in June 26th issue, after enumerating the various advantages of plate girder construction, for example, simplicity and uniformity of construction, solidity and durability, speed in erection, and low office cost, went into the calculation of the stresses due to the loads. The methods by which the ordinary dead and live loads are obtained do not form a part of the article as the reader may refer to any authoritative text on the subject for them. Following, the various sections of material to be used in design are next in consideration.

The web plate is first determined, as its depth is already decided, and 10,000 pounds per square inch of gross section is the unit which is generally used in obtaining the required thickness of web. It may, however, be necessary in some cases, to use a thicker web than is required by this unit in order that the end shear may be transmitted to the flange angles in a length equal to the depth of the girder. This is only probable when the web is connected to the flanges by single lines of rivets and the number of rivets is, therefore, more limited.

The flanges of girders are determined, as in trusses, by dividing the total bending moment at any point by the product of the effective depth and the unit tensile stress. The difference between girders and trusses is that the flange stress varies gradually throughout the length of the girders, while in trusses it is constant between panel points. The bottom flange is usually figured at 16,000 pounds per square inch of net section, and the top flange is made the same total gross section as the bottom, with the restriction that the unsupported length of the flange must not exceed twelve times its width. This limits the spacing of floor beams and cross-brace frames.

As the centre of gravity of flanges cannot be known until the sections are determined, a great amount of time is usually wasted in assuming a centre of gravity and making approximate calculations, and this operation repeated several times until the section is finally settled. Table 1 gives a useful table for railway girders. By use of it the required flange can be determined by one calculation and the labor of figuring the net sections and centre of gravity is avoided.

The effective depth used should never be greater than the distance, back to back, of flange angles.

There is a wide diversity of opinion among engineers as to whether part of the web should be counted as flange area. For this to be so, the flanges and web must act as a solid beam and theoretically ⅙ of the gross section of web would act as flange section, but it is considered to be ⅛ on account of deduction of rivet holes.

Since the bending stresses in the web do not act at any one point, but over the total depth of the web, having a maximum intensity at the edge of the web and zero at the centre, it is very difficult to properly splice the webs to take care of these stresses. It involves a great many rivets and extra material, which, in cases of heavy girders, is worth more than the material saved in the flanges. Moreover, if the web is considered to take tension, it is good practice to plane its edges to avoid tearing, and this is additional expense.

In some cases where the web does not need to be spliced, owing to possible lengths that can be procured from the mills, there would be a saving of material and cost, to consider ⅛ of the web as flange section. But, since it is only an assumption that the girder acts as a solid beam, and since the flanges are figured the same as in trusses, it seems advisable to consider that the web resists shear only; the only difference being that the web acts continuously instead of at panel points. The top flange of deck plate girders is often made an H-shaped section of four angles and side plates. The main advantage of this section is its suitability to easy framing of the deck ties, as there are no rivets or cover plates to be taken care of. The objections to such a section are, that it is more difficult to manufacture, because extra drawings are necessary and the shop work is more expensive; this for the reason that in modern shops equipped with spacing tables, it is a big advantage to have both flanges similar. Moreover, the H-flange is not as strong to resist buckling from handling and from compression stresses, as is the more common section composed of two angles and cover plates. Hence, if it is used, the brace frames should be made with the top strut the same depth as the flange section. This is necessary because the top laterals are at the elevation of the bottom of the H-section, which is some distance below the deck, and because the web stiffener angles must break at the bottom of the H-shaped flange, which is a marked weakness.

Stiffener Angles.—These are an important factor in the strength of girders and, as their duty is not generally understood, they deserve some explanation. They may be divided into two classes, viz., those that resist concentrated loads and those which merely prevent web buckling. The end

stiffeners transmit the total end reaction to the web plate where it is converted into shearing stresses. As these stiffener angles are ground to fit the curved fillet of the flange angles, it is evident that a large part of the reaction is transmitted to the stiffeners by direct bearing of the outstanding leg on the flange angles, and it is therefore necessary to have this leg as wide as the flange angles will permit, and care should be exercised in the shop to ensure that these angles have an exact fit and true hearing. In arriving at the sections

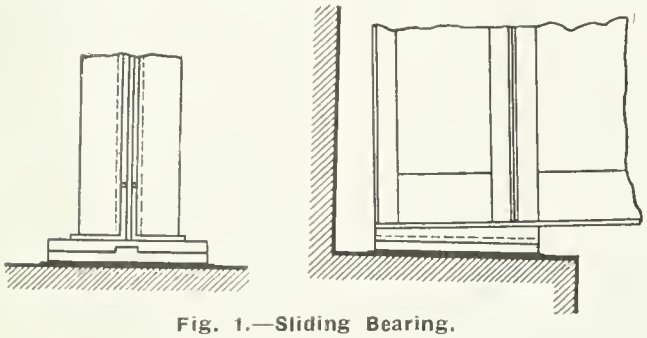

Fig. 1.—Sliding Bearing.

of end stiffeners, it is usual to consider that they act in conjunction with the filler plates, as a column of length equal to the depth of the girder, and that the end reaction produces a compression which is constant throughout the length of the column, whereas in reality, the stress diminishes from a maximum at the bottom to zero at the top. As the filler plates cannot be considered to bear on the flange angles in actual practice, the stiffener angles must take the entire stress at the break between the filler and toe of the flange angles; and it is at, or below this point, that the failure of end stiffeners would usually occur. Taking this into account, and also the fact that the bearing of the outstanding leg does not transmit all the end reaction, but that part of it will go into the other leg through bearing on the fillet and rivets at the bottom, it is a common practice to use end stiffener angles, the gross

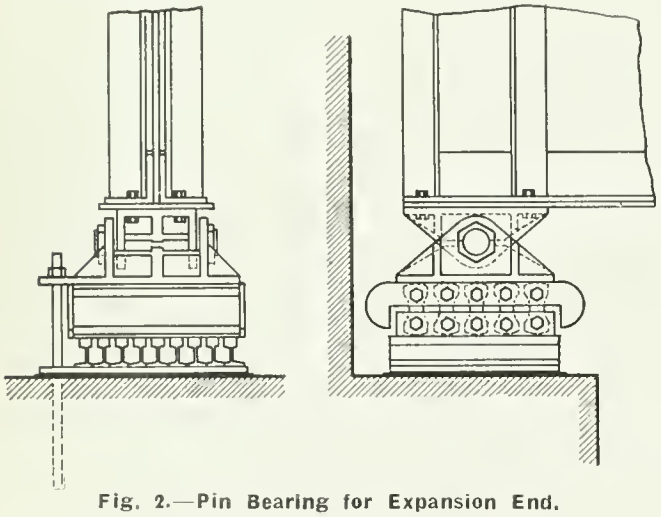

Fig. 2.—Pin Bearing for Expansion End.

section of which is considered to resist the reaction at 12,000 pounds per square inch. In addition to these considerations, the designer must use judgment in the selection of the angles, so that the outstanding leg will be thick enough to prevent its buckling near the bottom, where it is highly stressed. There should also be sufficient rivets connecting these stiffeners to the web to transmit the reaction intended.

Intermediate stiffeners which are merely intended to prevent the web plate from buckling, do not cause the designers of girders much worry, as all railroads have adopted standard sections for different depths of girders and certain limitations as to the spacing of them, but it is a satisfaction to know that their failure in actual structures has been very rare. They have been generally determined by formulae based on compression in the web plate due to shearing forces acting upon it. This seems the most reasonable method. The spacing of these intermediate stiffeners should therefore depend on the shearing stresses, and this would necessitate their being spaced closer towards the end of the girder.

Theoretically there is no reason for the intermediate stiffener angles to bear on the bottom flange, but it is always done in practice and makes a neater job. It is necessary, however, in the top flanges because it tends to prevent the outstanding leg of the flange angles from buckling and in deck girders it helps to transmit the loads from the track into the web plate.

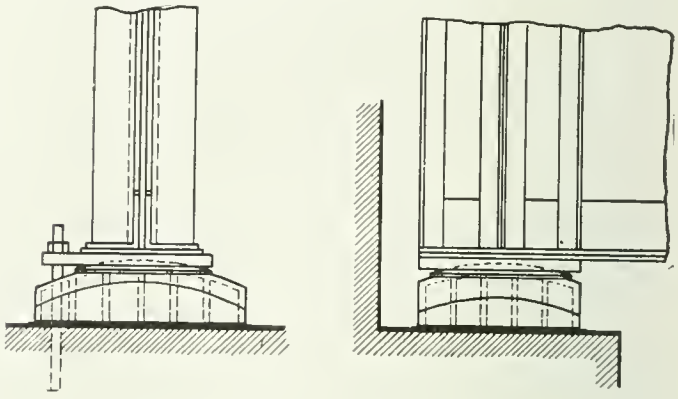

Fig. 3.—Disc Bearing for Fixed End.

Pier Members.—They are determined in area, by the unit, 400 pounds per square inch for concrete masonry. For spans up to 75 feet in length sliding masonry plates only are used, as indicated in Fig. 1, with a tongue and groove to resist side motion. The groove should be on the upper shoe plate as shown, so that dirt and water cannot lodge in it.

With this type of bearing it is advisable to consider that the stiffeners over the inside edge might have to take 75 per cent. of the total end reaction, because any deflection in the span tends to move the end reaction to this point.

For spans 75 feet long or over, pedestals are necessary to properly distribute the bearing pressure, and to adjust themselves to deflection and camber. Fig. 2 indicates the pin type which is generally used in the United States, and it may be made up of structural shapes, or cast steel. By means of the pin the bridge is securely anchored to the bottom pedestal.

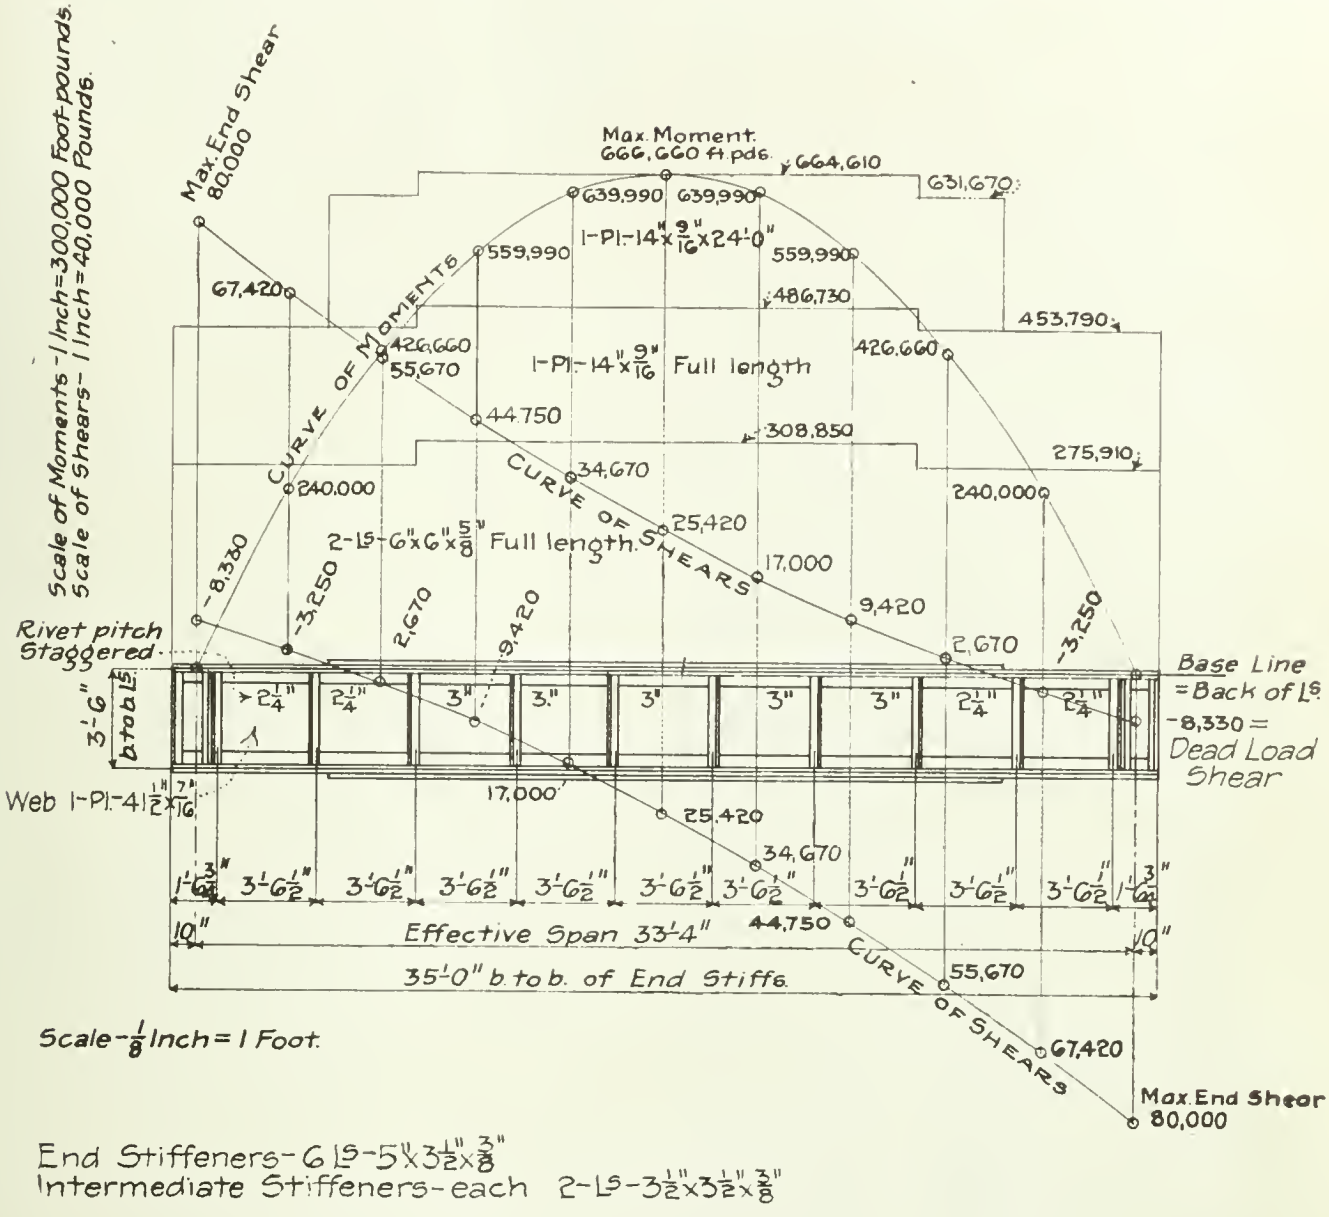
Nearly all Canadian railroads use the disc bearing, as shown in Fig. 3, and it is superior to the pin type in many ways. It is sure to have a true bearing, as it adjusts itself in all directions to suit uneven masonry and deflection in the span. It is also convenient in erection as the girders can be dropped into place with a minimum trouble in adjustment.

In the disc type most of the end reaction should he considered to enter the girder over the centre of the disc with a small proportion at each edge, while in the pin type, where the shoe is deeper, all the end stiffeners can he considered to take an equal share.

Expansion in Girders.—This condition should be provided for to the extent of one inch for each 80 feet of span, and for all spans over 75 feet in length roller nests must be used at one end. These should be constructed so that the sides may be taken off and the rollers cleaned and oiled; also in such a way that they will shut out as much dirt as possible and not hold water. Fig. 2 represents a good design

for roller nests, in which segmental rollers are indicated, the lower bearing surface being a nest of rails. The segmental rollers are convenient because they occupy a minimum space for a large diameter. The rails are important because dust will not lie under the rollers, but will fall through, affording easy removal. Bearing plates should always be made thicker, to allow for rust of ½ inch in thickness.

Stringers and Floor Beams.—These constitute the floor system in through plate girder spans. As the stringers are merely deck girders of reduced length, their design is similar. They should be made as deep as practicable, and should be riveted to the webs of the floor beams. Two lines of stringers per track is good practice, but four lines are more able to resist derailed trains, and do not require such large ties.



End Stiffeners - 6 L's - 5" x 3½" x ⅜"
Intermediate Stiffeners - each 2 - L's - 3½" x 3½" x ⅜"

Fig. 4.—Stress and Section Diagram for Deck Plate Girder.

Lateral Angles.—Usually these are made heavier than the stresses require, to ensure stiffness of the bridge. In deck spans the entire lateral forces are considered to be carried by the top laterals, through the end brace frames to the anchors, while the bottom laterals are merely considered to stiffen the bottom flanges against wind. The latter are often omitted in deck spans under 50 feet long, as the interior brace frames give sufficient stiffness to the bottom flange.

In through plate girder spans there is only one system of bracing, which necessarily carries all the lateral stresses, and the traction stresses in addition.

When rods are used as laterals, an initial stress of 10,000 pounds should be added to the other stresses to take care of the tension induced in the rods by tightening the nuts or turnbuckles.

With four lines of stringers, the common method is to assume that the inner and outer stringers take their share of the wheel loads inversely in proportior to the distance they are spaced from the rail. As a matter of fact, when the rail is midway, the inner stringer gets a greater proportion of the wheel load, because the ties are continuous beams over four supports. Some account should be taken of this.

Floor beams should also be made as deep as practicable. When the top flange is of moderate width it should be about one inch below the base of rail, so that it will support derailed trains; but when the top flange is 18 in. or 20 in. wide, it is good practice to drop it three inches below the base of rail, so that a wood strip can be placed on it to support the rail, as well as to be useful in the event of wheels passing over it.

Stress and Section Diagrams.—Such diagrams are convenient for reference on bridge plans, indicating graphically the bending moments and shears along the length of the span, and the flange and web sections which correspond. Fig. 4 shows a complete form, and needs little explanation. The two shear diagrams represent the change in web shear as the train passes over the bridge in either direction, the live load and impact shear changing, while the dead load shears remain unchanged. These curves determine the required web section and the web flange rivet spacing.

The bending moment diagram determines the required flange areas and the length of cover plates. These plates are made to pass beyond the curve far enough to develop the strength of the plate in rivet connections. When the flange rivet spacing is less than 2½ inches, staggered, it is considered that two extra rivet holes are deducted from the net flange area, which explains the drop in the area lines shown in the diagram. Where web and flange splices are necessary this diagram is convenient for reference in getting out detail drawings.

The Design of Trough Floors.—The computation is different from that of regular plate girders, as the section is determined by their net moment of inertia, as in the case of a solid beam. When the troughs run parallel to the line of track, the axle loads are assumed to be distributed in a width of nine feet, which is the length of the ties, and this decides the amount of load carried on each trough. When the troughs run normal to the line of track, the axle load should be considered distributed over three ties of nine feet in length. A minimum thickness of 7/16 inch is recommended in trough floors to resist rust, and the surface to be covered with concrete should be left unpainted in order that the concrete will adhere better.

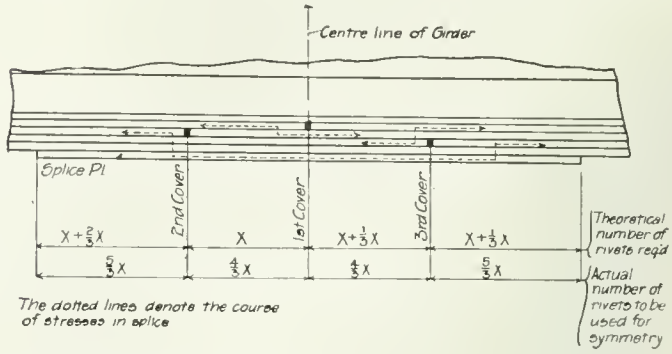

Fig. 5.—Flange Splice.

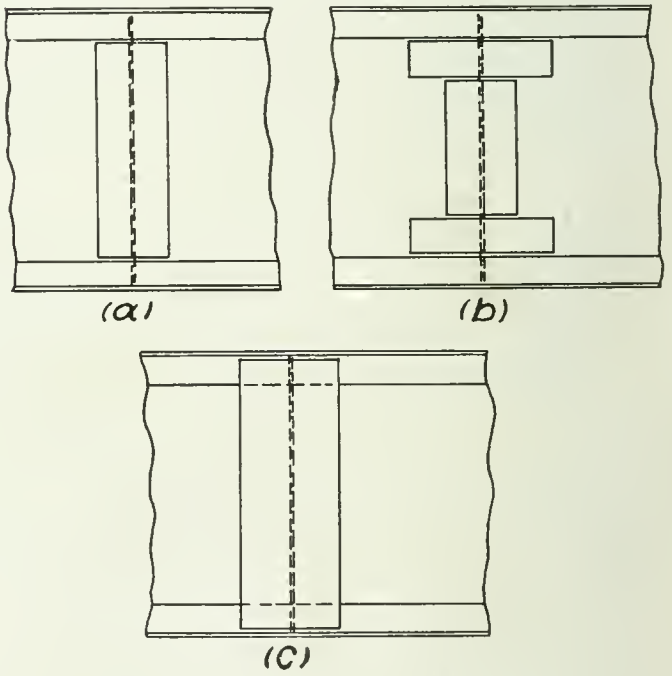

Fig. 6.—Plate Girder Web Splices.

Fabrication of Sections.—The details in connection with the framing of the various sections of a bridge may be the cause of its failure, as the strength of a structure is measured by the strength of its weakest point. It is necessary for the detailer to have an intelligent grasp of the action of stress through rivets and sections and he must keep in mind the sizes and maximum lengths of material that can be procured from the mills. He must be familiar with shop practices and erection methods, and must also consider the conditions of exposure of the bridge in actual service.

Splices should be avoided where possible, by the use of the longest angles and plates that can be obtained. Flange splices should alternate except in special field splices where it is necessary to have a compact joint. The theory connected with flange splices can be best explained by an example and the reasoning used in it can be applied in all cases. In the example shown in Fig. 5 the flange consists of two angles and four cover plates, and it is required to splice the two angles and three plates. The first cover plate breaks at the centre of the girder, and the second and third at equal distances each side of the centre. For convenience, consider the cover plates to be of equal thickness, and a splice plate added on the outside., thick enough to splice any one plate. Let X denote the number of rivets, in single shear, required to develop each plate, and let the arrow lines represent the lines of stress from one plate to another. When the stresses

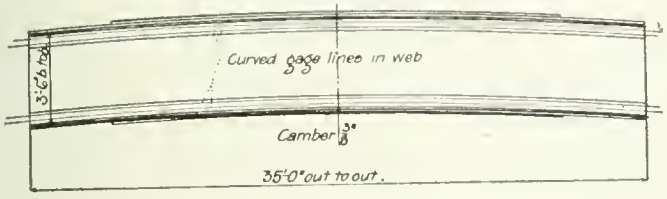

Fig. 7.—Plate Girder Without Web Splices Showing Camber.

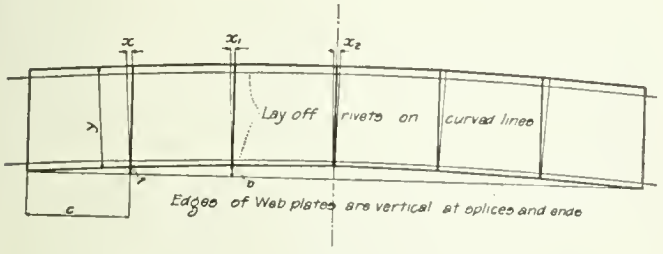

Fig. 8.—Plate Girder With Five Web Splices.

must pass through intervening plates, it is good practice to increase the number of rivets required by 33⅓ per cent. for each intervening plate, because the rivets are less efficient on that account. The number of rivets required theoretically is then obtained, as explained in the example, and in order to make the girders symmetrical about the centre line, extra rivets are added. To complete the splice the best arrangement is to break the flange angles just beyond the cover plate splices. They should alternate, one on each side of the centre line of girder. The number of rivets are obtained in the same way as for the cover plates. Where space is limited, the angles could be spliced in conjunction with the cover plates, but the method outlined above is better, because it does not require the use of such long rivets.

The Splicing of Web Plates.—This is a difficult detail and a subject of disagreement among engineers. If the web is considered to transfer shear only, the best solution for the splice, it to use a pair of splice plates of a depth equal to the clear distance between the flange angles, and attached with the necessary number of rivets, to properly develop the splice. This arrangement is indicated in Fig. 6 (a). If it is desirable to have the web carry its due proportion of the bending moment, this form of splice can also be used, but it is necessary to have a sufficient number of rivets in the connection to resist the web shears and also the amount of bending moment attributable to the web plates. This requires a large number of rivets and their value varies directly with the distance from the centre of the web plates.

A common form of splice is shown in Fig. 6 (b), in which the horizontal plates adjacent to the flange angles are considered to resist the bending moment, and the vertical plates to resist the shear. This is perhaps the cheapest arrangement, but not the best, for it concentrates the bending stresses at two points, whereas, in reality they occur over the entire depth of the girder; and it splices the web for shear, in a depth which is considerably less than the web, and thereby introduces unknown internal stresses. The horizontal plates are sometimes made to overlap the flange angles, but this arrangement has the same objections.

The splice shown in Fig. 6 (c) is recommended by some engineers as the best form of detail. It is similar to (a) except that the splice plates are extended over the flange angles and either crimped or placed on fillers. In this way the splice has the same depth as the web itself. This is expensive shop work, and requires a lot of rivets. It has the additional objection that the flange rivets in the splice are used in a double capacity, as they act with the splice and also have the same work to perform as all flange rivets.

Since there is evidently considerable uncertainty in the efficiency of web splices, where the web is considered to take bending stresses, it seems safer, as stated before, to consider that the web takes shearing stresses only. The best method, and one which is used by the Pennsylvania Railroad, is to use a splice which is considered sufficiently strong to develop the bending stresses, if ⅛ of the web acts as flange section, but to disregard the web in figuring the flange, by using sufficient flange section to resist the entire flange stress. In this way the factor of safety of the bridge is increased at very small cost, and this provides for future excessive loading.

Rivet Spacing.—The rivet spacing in flange angles is dependent upon the assumption that the shear at any cross section is transmitted into the flanges in a length equal to the depth of the girder. This depth should be considered the distance, centre to centre, of web flange rivets.

In the top flange of deck girders, there is also the direct load from the track to be considered, which makes the calculation more complicated. Some engineers consider that the axle load plus impact is supported by only two ties, but it is more common practice to consider that it is distributed over three ties. For an example, consider the case where none of the bending stresses is carried by the web plate, and assume that the direct load is distributed over 36 inches. As this distance is very short, the impact should be counted 100 per cent. of the live load. If W represents the combined wheel load plus impact, then W/36 will equal the vertical load per lineal inch on the flange rivets; and if S represents the shear in the girder at any cross section, S/h will equal the horizontal shear per lineal inch, where h is the depth.

The resultant stress on the rivets per lineal inch of flange will be $\sqrt{\left(\frac{W}{36}\right)^2 + \left(\frac{S}{h}\right)^2} = K$. The working value of one rivet in bearing on the web, divided by k, will give the required pitch of rivets in the web flange. This spacing is slightly less where ⅛ of the web acts as flange section because the entire shear does not have to be transmitted through the flange rivets.

The rivets in cover plates are spaced so that there will be a sufficient number between the ends of two successive plates to develop the strength of the longer one. This, however, usually gives too great a pitch, as practical reasons require a maximum allowable spacing in order that the surfaces will be held in even contact.

Camber in Girders.—As stated before, this is often specified, but it is only obtained by proper details. Where there are no web splices in the girder, it is necessary to punch the flange holes in the web plate in the form of a circle, as shown in Fig. 7, and the flange angles are pulled down to suit, when the girders are assembled in the shop.

When the web plate has splices at various points there are two methods of camber commonly used. In the first method, which is the cheaper and more common, the top and bottom flanges are considered as circles about a common centre. This is accomplished by adding the extra length required in the upper flange, at the points of web splice. This extra length is the same at each splice, and the web splice plates are detailed to suit.

The other method, which is used by the Pennsylvania and other railroads, is more to be commended, and is shown in Fig. 8. Here the upper and lower flanges have an equal radius and are of equal length, the ends of the girders being vertical. This arrangement has a big advantage in details and shop work. In the example given, the girder is 88 feet long over all, and requires a camber of 1 1/16 inches when figured at 1/1000 of the span. This would be increased by ⅛ of an inch for each web splice to allow for shop play, which makes a total required camber of 1 11/16 inches. For even figures 1¾ inches is considered.

The ordinates, a and b, are then figured at the various splice plates. By proportioning similar triangles, $X = \frac{a}{c} \times y$, and similarly Xl and X_2 are obtained. They diminish in value towards the centre of the girder. The web plates should be planed to these figured bevels, so that they will bear along the splice, and the splice plates are also detailed to suit. If the last method is used, and properly followed in the shop, good results should be obtained.

Many engineers put the same camber in the deck as in the girders, by using the same dap in the ties along the length of the span. The better practice is to take all camber out of the track for spans up to 75 feet, and to take out only one-half the camber for greater spans. This for the reason that the bridge looks better to have the track level under dead load only, and moreover, as there is always an excessive camber over that required to balance actual deflection from the ordinary fast trains, these trains would only produce a very slight dip in the track in passing; whereas, if the track had excessive camber, there would always be a bump which would be very objectionable in trains at high speed. With the heavier trains passing there might be a noticeable deflection, which would cause a dip in the track, but the heavy trains would be moving comparatively slowly, and this would not be a bad feature.

The ends of girders in deck spans are necessarily square at the top, in order to support the ties, but in through spans it is customary to curve the top flange for appearance. One method, as indicated in Fig. 9, is to round the corners in the form of a circle with a radius equal to ⅓ the depth of the girder. This is commonly done, and is a good detail as the web plate is not weakened, but the shop work is expensive as the angles must be bent hot and spliced.

Fig. 10 represents a detail which is a cheaper curve to make, as the radius is about 1½ times the depth of the girder. It is also more suitable to resist derailed trains, and cases are actually known where trains have hit the ends of such girders and skidded back on the ties. The main objection to this type of end is, that the web is shallow where the shearing stresses are greatest and it is necessary to reinforce the web by side plates, as indicated by "A" in the sketch. In this construction, and also in the case of girders where the bottom chord is bellied, an error is often made by detailers, as they neglect to add the horizontal plates marked "B" in the diagram. In other words, they reinforce the web against rupture from shear in a vertical plane, and forget that, in order to transmit the shear into the flanges in a length equal to the depth of the web, it is necessary to reinforce the web also against rupture in horizontal lines at the toes of the flange angles.

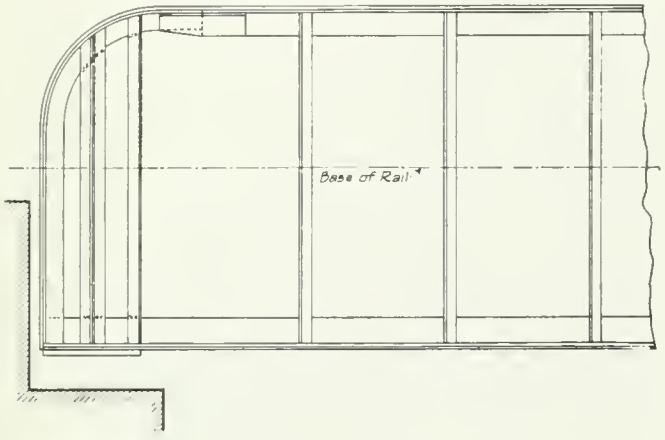

Fig. 9.—Curved End for Through Girder.

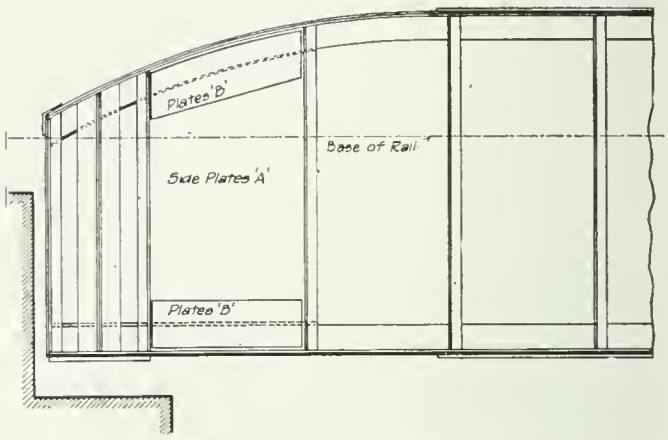

Fig. 10.—Curved End for Through Girder.

The grade of a track does not affect details of plate girder spans, except the sliding bearing plates of smaller spans, in which case either the upper shoe plate or the loose masonry plate must be planed on the bevel. Where the loose plate is bevelled the sliding plane is in the same direction as the expansion, which is an advantage where the grade is steep and the span is long; because if the upper shoe were bevelled there might be considerable rise and fall in the elevation of the track, when the bridge expands.

For smaller spans and light grades the best arrangement is to bevel the upper shoe, and thus keep the sliding surfaces horizontal, as shown in Fig. 1. Thus any tendency for the span to creep on a sloping surface is avoided.

Modern Methods in Shop Practice.—Shop methods, as well as the action of stresses and the strength of connections, should be well understood by the designer and detailer. Rivets should be spaced to suit the requirements of the spacing tables and multiple punches in common use, and which are specially adapted to plate girder construction. In this way the necessity for templates is reduced to a minimum and the shop costs are lowered.

Bridges should be so made that there is easy access for painting of all parts and no openings or pockets should be left where dirt and water might lodge.

In shipment, plate girders are sometimes troublesome and more expensive than other forms of lading. Where the girders are short and shallow and can be loaded on one car,

the method of loading is not very different from any form of heavy material. Where the girders are over sixty feet long and extend over two or more cars, it is necessary to adopt special pivoted bolsters in order that the cars will pass freely around curves. The bolster adopted by the Master Car Builders' Association, is recommended in practice and is explained in Figs. 11 and 12. The sizes of material given, are for girders weighing between 30,000 and 70,000 pounds, and vary slightly for other weights.

The weight of loading that can be placed on each car, where the load rests on one bearing point per car, varies from ½ to ⅔ of the capacity of car, depending on whether it is located at the centre or whether it is located midway between the centre and the position of the truck, and also depending on the construction of the car. The height of an ordinary flat car above the top of rail, is four feet and two inches, and this, in conjunction with the bolster, should be deducted from the minimum allowable overhead clearance along the line of shipment, in order to find the maximum depth of girder that can be shipped to various sites.

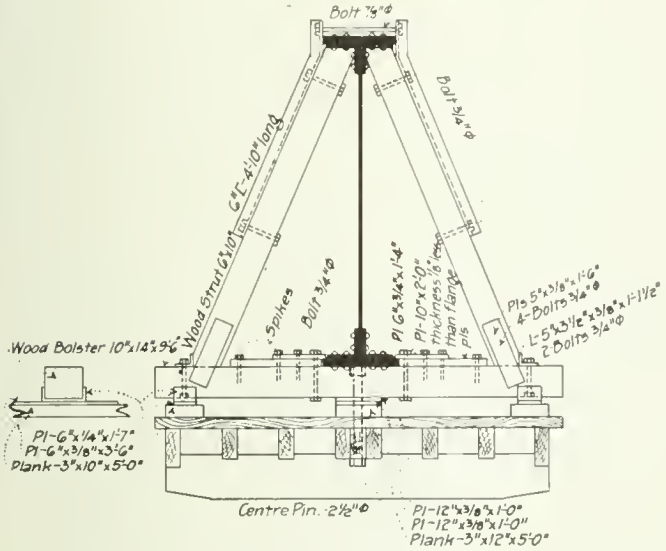

Fig. 11.—Method of Loading Girder on Flat Car.

The Erection of Plate Girder Spans.—This is accomplished with less expense and in shorter time than in the case of any other form of bridge. As it is an inestimable advantage in railroad construction to replace existing spans with no interference with traffic, the simplicity in erection of plate girder spans by modern methods is most important.

The old methods of erecting girders, where there was no falsework, was to place a gin pole in the centre of the span and gradually work the girders from the bank into position. Where there was falsework in place, which had been necessary for further construction of the road, there were several familiar methods employed. One was skidding the girders on the falsework and lowering by jacks. Another method was placing gantries at the abutments, or on cars, and from these gantries a set of falls was suspended which raised the girders off the cars, after they had been run out on the falsework, and which then lowered the girders into position. Lever cars and wood travellers were also used to lift the girders upon the falsework, after which they were pulled over into position.

The above-mentioned methods were dangerous and slow, and the modern erection car completely equipped, and properly manned, will take a plate girder span which is all riveted up, and drop it into position in less than one-half hour. Some companies use travellers which run on special wide-gauge tracks, but they require special provision in the design of the bridge to provide for this. The Hamilton Bridge Works Company, Limited, have eight erection cars in operation, which run on regular gauge tracks and, therefore, require little delay in rigging up at the site, requiring no provision in the design of the bridge, except that it is necessary to consider the load on the front trucks of the car. This very rarely affects the design, however.

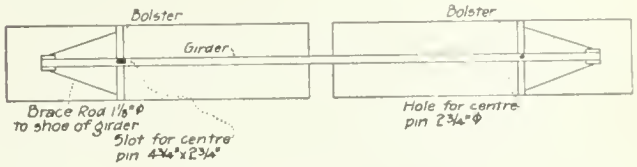

Fig. 12.—Plan of Loading.

Another advantage in the erection of plate girder bridges is that there are very few field rivets to be driven owing to the fact that the girders can be shipped completely riveted up. This is a big saving in costs, and is stronger construction, since rivets can be driven better in the shops, where machines are power-driven.

The evolution in plate girder bridges has been very pronounced since the year 1850, when they were first built of iron, and the principles of economy in design have changed to a great extent. It is impossible to foresee what changes will develop in the future, in regard to the limiting sizes that will be practicable; the composition and strength of metal that may be used, and the facilities for fabrication and erection that may be invented. For these reasons, the engineer in practice should be daily reminded that no set of specifications can cover all the questions he will have to decide, and that "The most perfect system of rules to insure success must be interpreted upon the broad grounds of professional intelligence and common sense."

THE PRODUCTION OF LIMESTONE IN CANADA.

The statistics given in the annual report of the mineral production of Canada, by John McLeish, B.A., do not include the value of the stone burned into lime by the quarry operators nor that of the stone used in the manufacture of cement, a record of lime and cement production being separately given. With these exceptions, the total value of the production of limestone in Canada in 1911 was $2,594,926, as compared with a value of $2,249,576 in 1910, or an increase of about 15 per cent.

There was a decrease in the production of limestone for building and monumental purposes and for curbstone and paving, but an increased production of crushed stone and rubble. The production of furnace flux was slightly less in tonnage, but of increased value.

The production during 1911 of limestone for building purposes was valued at $664,148, as against $695,729 in 1910. The value of crushed stone in 1911 was $1,066,559, as against $701,556 in the previous year. Curbstone and paving blocks were produced to the value of $36,902 in 1911, as compared with $125,637 in 1910. The value of rubble in 1911 was $374,327, as against $295,168 in 1910. The production of furnace flux in 1911 was 874,224 tons, valued at $452,990, as compared with 896,677 tons, valued at $431,486 in 1910.

CONCLUSIONS REGARDING MACADAM ROAD CONSTRUCTION.

Of the 1,001,823 square yards of experimental roads constructed by the Illinois Highway Commission, of which Mr. A. N. Johnson is engineer, 651,123 square yards were water bound macadam and 288,971 were bituminous macadam. A recently-issued report of the commission explains the construction of these experimental roads as an endeavor to determine the modifications necessary to adapt the usual methods of macadam construction to the particular conditions of soil, etc., encountered in the State of Illinois. With this end in view, frequent inspections have been made of all experimental roads built by the commission and information has been obtained as to their condition from year to year. As a result of this experience the following conclusions as to waterbound macadam and bituminous macadam under Illinois conditions are given.

Thickness and Width.—Roads have been constructed of varying thicknesses, sometimes because the local officials felt that on account of the cheapness of the stone, it would be as well to use plenty of it, and sometimes it was desired to demonstrate the possibility of economical construction by reducing the thickness of the stone where local conditions would warrant. The thickness has varied from 5 ins. to 12 ins., after being thoroughly compacted. Inspections made on these various roads from time to time show conclusively that there is no soil encountered in Illinois upon which it is necessary to use a thickness of crushed stone greater than 8 ins. after being rolled and have also shown there are many types of sandy soil in the State upon which a layer of stone 6 ins. thick will serve all purposes of traffic.

The width of roadway has also been varied considerably on the various sections of the road, the widths built being from 10 ft. to 30 ft. Observations of these roads under traffic indicates that there are very few places in the State where a roadway 10 ft. wide is sufficient. A road which does not have any large amount of traffic before improvement will, after improvement, attract a great deal of traffic, and consequently require a wider road than seems necessary from the traffic observed before improvement.

It is also apparent that roads constructed in the vicinity of cities of from 10,000 population upwards, should be wider than 12 ft. This is particularly true if the road will be subjected to any considerable amount of motor traffic, as is often the case in the vicinity of a city. These roads should be at least 16 or 18 ft. wide in order to accommodate both the motor and horse drawn traffic. While it may not seem desirable to build roads merely for motor traffic, yet it is evident that the motor traffic is here and must be taken into account in any comprehensive system of road improvement.

In general it can be said that in most communities where it is worth while to construct and improve roadways at all, a width of 12 ft. is desirable. And in many communities the roadways must necessarily be 16 to 18 ft. wide in order properly to accommodate the traffic which will use them. Moreover, the traffic census which has been taken by the Illinois Highway Commission during the past six years, shows that there is a large increase in motor traffic on these improved roads from year to year, and consequently a road which might be wide enough upon completion will be too narrow to accommodate the traffic in a few years.

Waterbound Macadam.—In regard to waterbound macadam construction, it may be remarked in general that there has been no difficulty, if reasonable precautions are taken for proper drainage, to support this form of construction on any of the soil conditions usually encountered in the State. Wherever isolated sections of macadam roads are exposed to mud marks tracked on at the ends and from adjoining roads, a disproportionate amount of damage is done, to that done on a larger mileage of road. The most serious damage to any of the macadam roads has resulted from tracking on of sticky mud, particularly the first year, before the road has become thoroughly seasoned and consolidated. The mud will pick out the binder and loosen the stone which will be carried with the mud on the wheels and deposited upon the road, which, when dry leaves the surface very uneven. Such action will be in evidence for 100 to 300 ft. from either end of the road.

It has been found, however, that if sand or gravel is placed on the earth roads adjacent to the macadam for 100 or 200 ft., that it will render the mud non-sticky and no damage is done to the macadam surface. If precautions of this nature are taken for the first and second winters, there does not seem to be much further difficulty experienced from this source, as the road in the meantime will have become thoroughly compacted and does not pick up.

Some roads have been much more affected by traffic than others, although it is a fact that the roads that have worn the best in some instances have carried the largest amount of traffic. On the roads with the lesser amount of traffic, it is usually the case that one vehicle follows the other, the majority of which have narrow tires, and all the wheels use a narrow space practically within 10 ins. in width. Where traffic uses a road in this manner, a rut or depression will form within a very short time after the road is thrown open to travel, and unless this depression is removed, practically every vehicle will follow in the track thus made.

If the incipient track is filled with a bonding gravel, the team traffic will avoid it, turning first to one side and then the other, according to the direction it may be going, and eventually consolidate the surface of the road. Wherever it is possible once to distribute the traffic over the whole road, there seems but little difficulty from the formation of ruts or concentration of wear in one track. Roads, however, that carry automobile traffic even in very limited amounts are difficult to repair in this manner, as the loose gravel will be soon thrown out by the motor traffic.

It has been found that a limestone road bonded with gravel to make a gravel surface is a very much better wearing road and will carry with less damage to the surface a very considerable amount more of motor traffic than a limestone road bonded with limestone screenings alone. It is to be noted that the damage done to a macadam road the first year is much more than during subsequent years. In general, if a small amount of gravel is distributed over the surface early in the first spring, the amount required being about one carload to the mile, and a drag is used on the road occasionally as wet weather permits, it is found that the road will pass through the next two or three seasons with little or no attention, save the occasional use of the drag during late fall or early spring.

With the majority of the roads built by the Commission, however, the general impression has been that such construction is permanent in a strict sense of the word, and once a road is built that nothing further needs be done. Thus very few of the roads have had any proper attention, so that their condition in many instances is much poorer than would have been the case under proper and systematic maintenance. As a result, when maintenance repairs have been made, the condition of the road is such that a very considerable amount of work is necessary to restore the surface, so that when this cost is distributed over the years which the road has been in use, the cost per year is often greater than would have been the case had a small amount of work been done more frequently, and the road surface in the meantime maintained in a much higher state of preservation.

In general, it may be said that waterbound macadam construction, particularly where gravel is used for the surface dressing, is a practical form of road construction for many miles of moderately traveled roads in the State; roads that carry a sufficient amount of traffic to make their improvement in this manner worth while at the same time have not developed an amount of motor traffic to prevent the maintenance of this form of construction at a reasonable cost. This applies particularly on those roads which eventually would become feeders to main roads where it is believed that this form of construction will prove serviceable for many years to come. But waterbound macadam is not advised on roads carrying a considerable amount of motor traffic or roads which will eventually become the main roads of a county or State system.

Table I.

Item.	Cost per sq. yd.	Cost per cu. yd.
Shaping roadbed, trimming shoulders and side roads	$0.03	.....
Applying bituminous binder	0.023	.....
Superintendence, watchmen, etc.	0.037	$0.12
Loading stone on wagons	.....	0.107
Spreading stone	0.028	0.093
Rolling and sprinkling	0.027	0.071

Bituminous Macadam.—The comparatively short experience that has been had with this form of construction with the work under the supervision of the Illinois Highway Commission and elsewhere, makes is impossible to draw any final conclusions. The results, however, of the experience so far gained, seem to show:—

1. The necessity in this form of construction for as stable a foundation course as possible, and that probably the best method would be to lay the first course of the road as waterbound macadam, applying the bituminous top about 3 ins. thick the following season when the foundation course had become thoroughly well compacted.

2. The necessity for using durable material in the bituminous top, and where under the conditions that exist in Illinois, limestone alone is available, the material used for filling the voids and dressing the surface of the bituminous layers as they are applied, should be of washed gravel and torpedo sand. The particles of the gravel are made up for the most part of silicious material, which is the hardest material available, but where the rock of which the road is made is tough and hard, then rock chips could be substituted.

3. It is necessary that the bituminous binder be spread so as to present as uniform a service as possible. This may not necessarily mean the uniform distribution of the binder as the texture of the surface of the macadam before the application of the binder may itself not be quite uniform. Therefore, the more finely divided form in which the asphalt can be applied, the better the control of its distribution. The form of the application whereby the material is spread by a jet of steam has given excellent results.

4. Too much binder should not be used as it will result in a less stable layer of bituminous concrete than if sufficient binder is used only to fill the voids in the stone.

5. It is essential that the surface of the road have very close texture and that usually this cannot be secured in less than three applications except by an excessive amount of binder. The most economical and best results can be secured when the binder is put on in three applications.

6. The bitumens which do not possess some ductility at freezing temperature have not been satisfactory.

7. There is some evidence to show that certain bitumens of low ductility at ordinary temperature are seriously injured by mud that may be tracked upon the road, particularly if the soil is of highly alkaline character. There does not appear to be an equal amount of injury done by mud from soils of slightly acid character, though in either case the results are not as satisfactory as with bitumens possessing higher ductility. It is important that bitumens be applied at high temperatures, and if possible, during hot weather, as some unsatisfactory results obtained can be attributed to the cold weather prevailing at the time of construction. The roads constructed with tar binder under ordinary traffic conditions seem to require a paint coat at the end of the second, or at the latest, during the third season, by which time the tar near the surface of the road seems to have lost most of its adhesive qualities.

Table II.—Estimated Cost of One Mile of Macadam Road.

			Average haul ½ mile		Average haul 1 mile		Average haul 2 miles		Average haul 3 miles	
Width ft.	Cu. yds. stone per mile	Sq. yds. per mile	Water-bound	Bitu-minous	Water-bound	Bitu-minous	Water-bound	Bitu-minous	Water-bound	Bitu-minous
12	2,200	7,040	$4,572	$ 5,859	$4,836	$ 6,123	$5,298	$ 6,585	$ 5,870	$ 7,157
16	2,637	9,387	5,659	7,375	5,875	7,591	6 429	8,145	7,115	8,831
18	2,805	10,560	5,960	7,892	6,297	8,229	6,886	8,818	7,615	9,547
20	3,116	11,733	6,624	8,770	6,995	9,141	7,649	9,795	8,459	10,605
24	3,740	14,080	7,948	10,524	8,397	10,973	9,182	11,758	10,154	12,730

8. A tar with approximately the following analysis has proved most satisfactory:—

Specific Gravity.—The specific gravity at 25° C shall not be more than 1.26.

Free Carbon.—The free carbon shall not exceed 20 per cent. by weight.

Consistency.—The consistency as determined by the Howard and Morse float appartus at a temperature of 50° C shall not be less than 1½ mins. nor more than 2½ mins.

Distillation.—Fractional distillation shall give results within the following limits, all measurements being by volume.

Up to 110° C the distillate shall not exceed 2 per cent. and shall be free from ammoniacal water.

Up to 170° C there shall be not to exceed 5 per cent. distillate, of which not more than one-fourth shall be naphthalene.

The total distillate up to 315° C. shall be at least 18 per cent.

Brittleness.—A cylindrical prism of the tar binder 1 cm. in diameter, after being maintained at a temperature of 0° C for 20 mins., shall bend into a semi-circle of 3 cm. diameter without checking or breaking.

9. A surface constructed with an asphalt binder apparently requires a paint coat during the third or fourth season. While the asphalt binders do not seem to lose their adhesiveness, the mat forming the close texture of the surface under ordinary traffic conditions will have become worn so as to make the application of a paint coat desirable as a protection against further wear of the road. The most satisfactory results with asphalt binders were obtained with those having closely the following analysis:

Class A.—Bituminous binders shall conform to the following specifications, the various properties described being determined by the methods proposed by the American Society for Testing Materials:

1. The material shall be free from water.

2. **Specific Gravity.**—The specific gravity at 25° C./25° C. (77° F.) shall not be less than unity.

3. **Total Bitumen.**—The bituminous material shall be soluble in chemically pure carbon bisulphide at air temperature to the extent of at least 99.5 per cent. for residuums and gilsonite products, 95 per cent. for Bermudez products, 80 per cent. for Cuban products, and 65 per cent. for Trinidad products.

4. **Naphtha Insoluble Bitumen.**—Of the total bitumen not less than 15 nor more than 28 per cent. by weight shall be insoluble in 86° B paraffine naphtha at air temperature. On evaporation of the naphtha solution the residue obtained shall be sticky and not merely oily.

5. **Fixed Carbon.**—The fixed carbon shall be not less than 8 nor more than 14 per cent.

6. **Penetration.**—The penetration as determined with the Dow penetration machine, using a No. 2 needle, 100 grams weight, 5 sec. time, and a temperature of 25° C (77° F) shall not be less than 12 mm., nor more than 16 mm.

7. **Loss on Evaporation.**—When 20 grams (in a tin dish 2⅜ ins. in diameter and ¾ in. deep with vertical sides) are maintained at a temperature of 170° C (338° F) for 5 hours in a New York testing laboratory oven, the loss shall not exceed 6 per cent. by weight. The surface of the residue at air temperature shall be smooth and show no sign of blistering or cracking, and when tested with the Dow penetration machine for 5 secs. at 25° C (77° F) with a No. 2 needle, and 100 grams weight, it should have a penetration of at least 5 mm.

8. **Ductility Test.**—The ductility at 25° C (77° F) shall not exceed 85 cm., according to the district of Columbia standard.

9. **Flash Test.**—The flash point in an open cup shall not be less than 163° C (325° F).

10. **Paraffine Scale.**—The asphaltic binder shall not contain more than 2 per cent. by weight of paraffine scale.

Class B bituminous binders shall conform to the following specifications, the various properties described being determined by the methods proposed by the American Society for Testing Materials:—

1. The bituminous material shall be free from water.

2. **Specific Gravity.**—The specific gravity at 25° C / 25° C (77° F) shall not be less than 0.965 nor more than unity.

3. **Total Bitumen.**—The bituminous material shall be soluble in chemically pure carbon-bisulphide to the extent of at least 99.5 per cent. by weight at air temperature.

4. **Naphtha Insoluble Bitumen.**—Of the total bitumen not less than 20 nor more than 26 per cent. by weight shall be insoluble in 86° B paraffine naphtha at air temperature. On evaporation of the naphtha solution, the residue obtained should be sticky and not merely oily.

5. **Loss on Evaporation.**—With 20 grams (in a tin dish 2⅜ in. in diameter and ¾ in. deep, with vertical sides) and maintained at a temperature of 163° C. (325° F.) for 5 hours in a New York testing laboratory oven, the loss shall not exceed 2 per cent. by weight. The surface of the residue at air temperature shall be smooth and shall present no greasy spots nor any sign of blistering or cracking. The penetration in the residue shall not be decreased more than 40 per cent. from the original consistency.

6. **Fixed Carbon.**—The fixed carbon shall not be less than 7 nor more than 13 per cent.

7. **Penetration.**—The penetration as determined with the Dow penetration machine, using a No. 2 needle, 100 grams weight, 5 secs. time, and a temperature of 25° C. (77° F.) shall not be less than 7 nor more than 12 mm.

8. **Paraffine Scale.**—The bituminous binder shall not contain more than 6 per cent. by weight of paraffine scale.

9. **Carbon-Tetrachloride Insoluble Bitumen.**—Of the total bitumen not more than 0.5 per cent. by weight shall be insoluble in chemically pure carbon-tetrachloride at air temperature.

10. **Brittleness Test.**—A cylindrical prism of the bituminous binder 1 cm. in diameter, after being maintained at a temperature of 5° C for 20 mins., shall bend in a semicircle of 3 cm. diameter without checking or breaking.

11. **Flash Test.**—The flash test in open cup shall not be less than 200° C (392° F).

12. **Melting Point.**—The melting point shall not be less than 60° C (140° F).

13. **Ductility.**—The ductility at 25° C shall not be less than 25 mm., according to the District of Columbia standard.

These binders are of two general classes, and it was found in practice that excellent results were obtained by using a mixture of three parts of low price blown oil or residual asphalt of class B combined with one part of a natural asphalt of class A.

10. The size of stone in the bituminous layer should range from 2½ ins. to ¾ ins. where limestone is used. When trap rock or other equally hard material is available, stone should not exceed 2 ins. in size; the chips for filling the stone not to exceed ¾ in. and the grit for the top dressing not to exceed ¼ in. and all of the materials to be free from dust.

11. The use of laboratory is absolutely necessary for making tests on materials and mixtures as construction proceeds.

12. Experience indicates that this form of construction is adapted to moderate traffic roads, that is, where there is no large amount of extra heavy hauling. Where the traffic is composed of automobiles and farm loads not to exceed two tons, this form of construction will prove satisfactory, although possibly not as durable as either concrete or brick. Where traffic consists of heavier loads, wholesale trucks, heavy coal hauling and loads reaching to five and six tons, it is believed this form of construction is not at all suitable.

It presents a pleasing appearance and is well adapted to horse drawn traffic, but requires close attention for maintenance, and there is some evidence that during warm weather, when the bitumen is least stable there is a tendency for the surface to creep and undulations develop.

The cost of this form of construction over that of first class waterbound macadam is approximately 20 cents per square yard, but there has not been had sumcient experience to determine definitely the maintenance cost and its final economy. The construction requires the utmost care in every detail, and owing to the small experience contractors have had with it, appreciation of this fact has not been realized, with the result that nearly everywhere work done under contract has not been as satisfactory as that done by day labor under the immediate supervision of skilled men. Where attention is given to the construction and where the services of a laboratory are available, to insure the character of the materials, there is no difficulty in duplicating results. Bituminous macadam is of doubtful value on those sections of road so situated that considerable quantities of mud will be tracked on them from adjoining roads.

Construction Cost of Macadam.—At the close of the season of 1912 there were available cost data obtained from the construction of about 150 separate pieces of road, involving the handling of 286,494 cu. yards of stone. A study of these data shows that the various unit costs are constant, regardless of the distance to the road from the tracks from which stone is hauled, except the cost per cubic yard for hauling stone. The costs of the various parts of the work shown in Table I., are the averages of these items for all of the roads constructed.

A study of the data on the cost of hauling stone shows that this cost increases constantly and almost uniformly from a distance of ¼ mile upwards. This variation is most readily shown by means of a curve which is given as Fig. 1. It is possible, with these data available, to make an estimate of the cost of the construction of a mile of macadam road for any length of haul for stone not exceeding three miles. When the width of a road and the thickness of the material have been decided, the fixed items of cost in the road can be immediately determined by use of the unit costs from Table I.

In this manner the estimates of cost of one mile of road, as given in Table II., have been made up. In the table, the cost of crushed stone is assumed to be $1.25 per cubic yard f.o.b., cars at the siding from which it is to be hauled. In bituminous macadam roads the cost of the bituminous binder is assumed to be 8 cents per gallon f.o.b., the siding from which it will be hauled, and it is also assumed that 2 gals. of binder per square yard of surface will be used. This table is based on the actual cost of the work which has been done by the Illinois Highway Commission, and makes no provisions for contractors' profits. It does, however, include cost of maintenance of equipment under the item of rolling and sprinkling.

It should be noted that the allowance for shaping the road bed, and trimming shoulders and side roads, while covering the ordinary earth work necessary on the average road encountered in Illinois, would not be a large enough allowance if the road to be improved included heavy earth work to reduce grades, or construct embankments.

The cost of labor on the various pieces of work varied from 30 cents to 50 cents per hour for teams and from 15 cents to 25 cents per hour for men, and the number of pieces of work where the lower price was paid was about as large as where the higher price was paid. It would probably be fair to assume that these costs are substantially correct where teams received 40 cents per hour, and men 20 cents per hour.

In Table II. the quantity of stone per mile is given and it will be noted that the quantity does not increase in proportion to the width. This is due to the fact that a road 12 ft. wide is made of uniform thickness, while the wider roads are made somewhat thinner at the edge than at the middle. The 12-ft road is estimated on a basis of thickness of 10 ins. of loose stone, while the 16-ft. road is assumed to be 10 ins. thick at the middle and 8 ins. thick at the edge, making the average thickness 9 ins. For roads wider than 16 ft., the average thickness has been taken as 8½ ins.

The cost of bituminous macadam roads exceeds the cost of waterbound macadam roads by the cost of the binder, plus the cost of application, and the experience of the Commission in the construction of bituminous macadam roads by the penetration method indicates that 2 gals. of binder per square yard of macadam is required.

MAINE HIGHWAY LAW.

Maine motorists are regarding the new highway law with mingled pleasure and pain. The pleasure part is experienced when it is considered that the bill provides that all trees must be removed from dangerous turns and at railroad crossings, and that no advertising signs can be erected within 500 feet of crossings. All state roads must be furnished with signposts of a uniform size and height, by the various towns. Part of the bill legislates against the motor truck, providing that trucks having a total weight of over nine tons must obtain a special license. Speed limits are set for all machines, ranging from fifteen miles an hour for light trucks to six for the heavy ones.

STONE PRODUCTION IN CANADA.

Statistics of stone production given in the annual report on the mineral production of Canada, by John McLeish, B.Sc., include the sales of all classes of stone used for building, monumental, and ornamental purposes, stone for paving purposes, curbstone, and flag-stone, rubble, rip-rap, and crushed stone, limestone for furnace flux, sugar factories, etc., but stone used for burning lime or the manufacture of cement is not included.

The kinds of stone quarried have been classed as granite, limestone, sandstone, and marble.

The records are practically confined to quarry operations or the production of sawn or polished stone when these operations are carried on by the quarry operators. In addition to this production of stone by regular operators, there is no doubt a large stone production by individuals, such as farmers and others, for house or barn foundations, concrete work, etc., of which it would be impracticable to obtain any satisfactory record. Much stone is probably also used in railway construction work and in road-building, of which no record has yet been obtained.

It is impossible, except in a few cases, to show the quantity of stone production, so that the value only of the shipment can be given.

The total value of the production of stone in 1911, according to returns received, was $4,328,757, as compared with a value of $3,650,019 in 1910, showing an increased production of $678,738, or 18.6 per cent.

The number of active firms reporting in 1911 was 191, the total number of men employed 5,437, and the total wages paid, $2,500,005. In 1910 the number of active firms reporting was 166, the number of men employed 5,105, and wages paid, $2,225,791.

Of the total value of the 1911 production, limestone contributed $2,594,926, or nearly 60 per cent.; granite, $1,119,865, or nearly 26 per cent.; sandstone, $451,183, or 10.4 per cent.; and marble, $162,783, or 3.8 per cent.

Stone was used for building purposes to the value of $1,368,693, or 31.6 per cent. of the total; monumental and ornamental stone, a value of $303,050, or 7 per cent.; curb, paving, and flagstone, $233,723, or 5.4 per cent.; rubble, $460,803, or 10.6 per cent.; crushed stone, $1,509,498, or 34.9 per cent.; and furnace flux, 874,224 tons, valued at $542,990, or 10.5 per cent.

By provinces, Quebec again shows the largest output, having a value of $1,894,892, or 43.8 per cent. of the total, being made up of limestone to the value of $1,296,577, granite valued at $462,678, marble, $135,187, and sandstone, $450. Ontario takes second place with a production of $892,305, or 20.6 per cent. of the total, of which limestone is credited with $680,461; granite, $131,816; sandstone, $54,032, and marble, $25,996. British Columbia ranked third in order of importance, with a total of $698,811, including granite, $460,851; sandstone, $179,580; limestone, $56,780, and marble, $1,600. The production in Manitoba was valued at $318,050, made up of limestone, $315,782, and granite, $2,268. The Nova Scotia production was valued at $292,914, comprising limestone, $245,216; granite, $24,258, and sandstone, $23,440. The Alberta production was reported as $158,344, all sandstone. New Brunswick is credited with $73,441, made up chiefly of sandstone and granite.

Official figures, recently compiled, place the cement production of the United States last year at 83,351,191 barrels, which is a new high record and an increase of more than 3,800,000 barrels in a year.

ALLOWABLE HEIGHTS AND AREAS FOR FACTORY BUILDINGS.*

By Ira H. Woolson, Mem. Am. Soc. M.E.

In the design of factory buildings, one of the vital eatures tending to control the spread of fire is a judicious imitation of height and area. It is self-evident that whatver restricts a fire reduces the life hazard. Owing to the upreme importance of these two subjects, a person contemlating the erection of a building of this class should give areful consideration to the history of fires in such buildings, nd the experience gained in fighting them. The question s more acute in this class of buildings than in any other ecause of the fire hazard which exists in them, and the conomic advantages due to reduced costs in construction nd supervision, when several large areas are housed under single roof. Just where to draw the line so as to produce easonable safety without prejudice to building investments s the problem.

Factory buildings of excessive heights or areas have ong been recognized by underwriting organizations as a grave danger to life and property, owing to the difficulty of controlling fires in them. They have for years urged limitaions which have been freely ignored by ambitious architects nd factory owners, because the suggested restrictions were considered unreasonably drastic. The evidence produced in his paper strongly supports the limitations which were dvocated.

It is logical to assume that the men best fitted to determine safe limits of heights and areas are the men who have made a life work of combatting fires under all conditions of weather and hazard. With this idea in mind, the writer communicated with all the fire marshals and fire chiefs in the United States representing cities of over 20,000 population. A set of eight questions and a letter of explanation were sent to each. Fire chiefs as a class are not good technical correspondents, therefore it was not surprising that only one-third of the men addressed responded to the appeal. However, replies were received from 117 representative cities well distributed as to size and geographical location. These have been summarized and form the basis of this paper. A few of the replies indicated a misunderstanding of the questions, and these were discarded. The questions were as follows:—

1. What should be the greatest height allowed for manufacturing or warehouse buildings **without sprinkler equipment?**

Brick and joist construction—
Height in ft. ..... or No. of Stories .....
Fireproof construction—
Height in ft. ..... or No. of Stories .....

2. Take the same question as No. 1, but assume the buildings to be fully equipped **with automatic sprinklers.** What height would you approve?

Brick and joist construction—
Height in ft. ..... or No. of Stories .....
Fireproof construction—
Height in ft. ..... or No. of Stories .....

3. What should be the greatest floor area allowed in the same class of building **without sprinkler equipment?**

Brick and joist construction—
Area in sq. ft. ..... or Width ..... ft. Length ..... ft.
Fireproof construction—
Area in sq. ft. ..... or Width ..... ft. Length ..... ft.

4. If the same buildings were fully equipped **with automatic sprinklers** what area would you approve?

Brick and joist construction—
Area in sq. ft. ..... or Width ..... ft. Length ..... ft.
Fireproof construction—
Area in sq. ft. ..... or Width ..... ft. Length ..... ft.

Each building was assumed as a good one of its class, with enclosed stairways and elevator shafts; and the chiefs were requested to base their answers upon experience in fighting fires in the class of buildings described, and to assume restrictions which would afford a reasonable chance of controlling a fire on any floor.

Naturally, and quite properly, the replies reflect the local conditions, such as the efficiency of the fire department, the water pressure, the combustibility of the goods being manufactured, the number of sprinkler equipments in service, and the degree of congestion among the buildings. However, all conditions were represented, and the summary of so large a number of opinions should indicate fairly well the average condition throughout the country. (See Table I.).

Table I.—General Average of 99 to 111 Replies Received From All Classes of Cities.[1]

Type of Building.	Stories in Height.	Area between Fire Walls in Sq. Ft.
Non-Fireproof, not Sprinklered..	3.1	6,300
Fireproof, not Sprinklered	4.9	12,300
Non-Fireproof, Sprinklered	4.6	12,800
Fireproof, Sprinklered	7.0	27,100

Average story height was 12 to 13 ft.

The answers regarding allowable heights were much more uniform than those relative to area. It is significant that 83 per cent. of the replies would limit the height of a fireproof sprinklered factory building to less than ten stories. The opinions in reference to height of the other classes of buildings were exceedingly uniform, and consistently low.

Replies as to permissible areas in sprinklered buildings were widely divergent, but for the unsprinklered classes they were more uniform than would naturally be expected considering the great diversity of conditions under which they were prepared.

It is evident from the figures given, that the fire chiefs have no settled policy among themselves as to the credit that should be given to an automatic sprinkler equipment as a fire extinguishing device. A few enthusiasts would permit unlimited area in a sprinklered building, while on the other hand a considerable number would give very little or no increase when sprinklers are installed. Two chiefs stated that their unfortunate experiences with sprinklers had caused them to lose faith in their reliability. As a whole, however, they are strongly in favor of sprinklers and are inclined to permit over generous areas in buildings so equipped.

In order that the replies may be intelligently interpreted they have been separated into three groups, Tables 2, 3, 4, according to size of the city represented, and each group has been analyzed to show the character of the answers given to each question.

In the cases referred to by an asterisk, where no limits to areas were given, they were not included in the averages, but were counted in the columns giving the number of answers above the average. In each group it will be noted that about the same number of men gave high answers to all questions, the proportion being one-quarter to one-half of the number in the group. The uniformity of height limits,

* From a paper read before the American Society of Mechanical Engineers in Baltimore, May 22nd, 1913.

[1] The variation in the number of replies (averaged) resulted from some incomplete answers.

and the lack of it in the area limits, is very apparent in all groups. It will be noted that the largest area values are given in Groups I. and II., comprising the smaller cities. This is significant, and needs explanation.

Table 2.—Group I. Summary of Answers from 52 Cities With a Population of 20,000 to 50,000.

Type of Building	Stories in Height			Answers above	Area in Square Ft.			Answers above
	Average	Max.	Min.	Average	Average	Max.	Min.	Average
Non-Fireproof, not Sprinklered....	2.8	6	1	13	6,000	20,000	1,150	15
Fireproof, not Sprinklered.....	4.4	10	2	24	12,600	60,000	1,150	15
Non-Fireprnof, Sprinklered....	4.1	8	2	17	12,300	*60,000	3,000	17
Fireproof, Sprinklered....	6.3	12	3	18	27,300	*180,000	5,000	20

* Four votes received in favour of "no limit to area" in this class.

Table 3.—Group II. Summary of Answers from 23 Cities With a Population of 50,000 to 100,000.

Type of Building	Stories in Height			Answers above	Area in Square Ft.			Answers above
	Average	Max.	Min.	Average	Average	Max.	Min.	Average
Non-Fireproof, not Sprinklered.....	3.2	6	1	8	8,300	40,000	2,500	5
Fireproof, not Sprinklered.....	5.2	10	1	6	14,800	60,000	2,400	4

Table 4.—Group III. Summary of Answers from 36 Cities With a Population of 100,000 and Over.

Type of Building	Stories in Height			Answers above	Area in Square Ft.			Answers above
	Average	Max.	Min.	Average	Average	Max.	Min.	Average
Non-Fireproof, not Sprinklered.....	3.5	7	1	17	5,400	10,000	900	15
Fireproof, not Sprinklered.....	5.3	9	2	18	9,800	22 500	2,400	10
Non-Fireproof, Sprinklered.....	5.0	10	3	15	11,300	22,500	900	13
Fireproof, Sprinklered.....	7.5	12	4	16	19,400	*80,000	2,500	9

* Two votes received in favour of "no limit to area" in this class.

Occasionally the fire chief of a small city has experience which would abundantly qualify him to estimate properly the merits of fireproof construction and sprinkler equipment; more often, however, his city has meagre protection of this kind, and consequently he has little opportunity to judge of their efficiency, and it is not strange that he should be a bit extravagant in the credit he would give them.

The most rigid restrictions on area are found in Group III embracing the large cities. As fireproof construction and sprinkler equipments are common in most of our larger cities, it is reasonable to assume that the fire chiefs of such cities would have had much more experience with such methods of protection, and be better able to decide what increase should b given in the size of a building when such protection is provided, than their less experienced fellow officers in smaller towns. It is thought quite proper to assume that their figures are more nearly correct and should be given the most weight.

Significant evidence in support of this argument is found in the fact that four chiefs who give no limit to areas in non-fireproof and fireproof sprinklered buildings are located in cities having a population of less than 50,000 in which there are few fireproof factory buildings or sprinkler equipments. On the other hand only two chiefs, in cities over 100,000 population, suggest a "no limit area" in a fireproof sprinklered building, and none approves such areas for non-fireproof buildings.

With these thoughts in view, Table 1 has been changed somewhat to be more in accord with the weight of evidence. It is believed, therefore, that Table 5 represents more correctly the consensus of opinion among the fire chiefs of the country best qualified to judge as to what should be the proper limits of height and area for factory buildings.

Table 5.—Allowable Heights and Areas in Factory Buildings.

Type of Building	Stories in Height	Area between Fire Walls in Sq. Ft.
Brick and joist construction, not sprinklered	3	6,000
Fireproof construction, not sprinklered.....	5	10,000
Brick and joist construction, sprinklered	5	13,000
Fireproof construction, sprinklered	7	20,000

These values might be increased somewhat under the influence of especially favorable local conditions, as previously explained, but the writer submits that as they represent the average deliberate judgment of such a large body of men, so well qualified to estimate the hazard which the values involve, they should be given careful consideration, and should be increased only with the utmost caution.

Extracts From Fire Chiefs' Letters.—The following extracts from letters received from different fire chiefs in connection with this investigation may be of interest as indicating their attitude of mind in relation to the questions asked:—

"In my opinion, from a fire-fighting standpoint, **no building** should be built over eight stories."

"In our city there is room to grow on the ground without building high in the air. It is almost impossible for a public fire department to fight a fire from the outside above 75 ft."

"The figures given mean that every 66 ft. by 66 ft. should have a brick wall through length of building with Underwriters' doors; same to be double. As for width, in no case over 66 ft. wide; with solid wall, same to reach above roof at least 6 ft. **Build on ground not in air.**"

"A building 8 or 10 stories high, out in the open where it can be attacked from all sides should be handled very readily by a modern equipped fire department."

"I think that a factory should never be more than four stories high. I almost feel that there is no such thing as fireproof construction from my own experience. I know that it is possible to store enough material in any building to burn it. I am very much in favor of dividing rooms in factories with fire-resisting walls, provided with automatic fire doors."

"While fireproof construction is the best, it is the contents placed therein that is the hazard to life and property. Buildings should not be constructed to a greater height than can be reached by fire department ladders; 85 ft. to upper windows."

"In my opinion no warehouse building ought to be over one story in height. In regard to manufacturing buildings, I will say that I do not approve of any of these buildings being over three stories in height. If they want room, let them build in length and not so high; that is just what makes such bad fires. These buildings have all kinds of combustible material in them and they are sure to jump to another building if they are four or five stories in height."

"It is my opinion that all buildings for manufacturing and warehouses should be sprinklered, and not built higher than what the water supply will furnish and cover."

"Do you think any fire department can successfully fight a large fire over six stories high, and ten stories allowed only when there are two sources of water supply with good pressure."

"Area of sprinklered and unsprinklered buildings should be about the same, on account of increase in height allowed for fireproof buildings."

"All buildings of character named should be sprinklered:"

"Joisted brick construction should not be allowed without sprinklers."

"I think a good sprinkler system is one of the best fire preventions that has been invented in a great many years, and if kept up properly, it is pretty hard for fires to get away."

"If I had my way I would not allow any manufacturing plant to do business until it were properly sprinklered. It does things when they should be done."

"My experience with the 28 factories in this city has been that the sprinkler systems are out of order much of the time. Not looked after properly.

"This department has had no unfortunate experience with the sprinkler system, but, I do not feel inclined to depend upon them."

"The reason for not showing more favor to sprinklered risks, is because our experience with sprinkler systems in this city has shown them to be unsatisfactory, and not to be depended on."

"Stairs should be of steel without any wood sides; if any wood in the construction then there should be sprinklers. Should be sprinklers in all elevators even if they are enclosed, for an elevator is a bad air shaft. Brick factories cut up with wooden partitions are generally hard fires to fight."

"I do not approve of small rooms in factories, they make it very hard for a fireman to fight his way through smoke trying to find a fire when a building of this kind is partitioned off so much."

"In considering the limiting of height and area of a building, the question of accessibility should play an important part."

OUTPUT OF LIME IN 1911.

The production of lime in Canada in 1911, as contained in the annual report of the Mineral Production of Canada, by J. McLeish, B.A., and according to returns received from the producers, was 7,533,525 bushels, this being the amount sold or used (equivalent to about 263,673 tons), and valued at $1,517,599, or an average of 20 cents per bushel, or $5.75 per ton.

The production in 1910 was reported as 5,848,146 bushels (204,685 tons), valued at $1,137,079, an average of 19 cents per bushel, thus showing an increased production in 1911 of 1,685,579 bushels, or 22 per cent.

Returns were received from seventy-five active firms in 1911, as compared with seventy firms in 1910. The average number of men employed was 1,056, and wages paid, $523,518, during the past year, as against 976 men employed and $466,876 paid in wages in 1910. Statistics of labor and wages should be used with discrimination, however, as many firms producing lime are also engaged in quarrying stone for purposes other than lime making, and are unable to make separate reports as to labor employed. This is particularly evident in the record for Nova Scotia and New Brunswick, since for the first mentioned the record includes only the labor employed at the kilns, while for the latter the quarry costs are also included.

The average price per bushel varied from a minimum of 16 cents in Ontario to a maximum of 34 cents in British Columbia.

Hydrated lime was produced by three firms only, the sales being 5,023 tons.

A small quantity of lime is annually made in Prince Edward Island. The production is separately shown for 1911, but for previous years is included in the Nova Scotia figures.

THE ELIMINATION OF TASTE IN TREATED DRINKING WATER.

Dr. Arthur Lederer, a chemist and bacteriologist in connection with the Sanitary District of Chicago, and Mr. Frank Bachmann, assistant chemist, in commenting upon the abundant use of chlorinated lime in the treatment of water supplies, refer, in a paper read at the fifth annual meeting of the Illinois Water Supply Association, last March, to the surprisingly little which has been done towards meeting with compliance the frequent complaints about the resulting taste.

The first experiments on the removal of taste due to chlorinated lime were made almost twenty years ago by Traube, who also was the first one to recommend it for the disinfection of water supplies, although its germicidal action was known before. Traube applied 4.26 mg. of chlorinated lime containing 1.06 mg. of available chlorine to one liter of the water, and added after two hours' contact 2.09 mg. of sodium sulphite ($Na_2SO_3.7H_2O$). He claimed that an excess of sulphite up to 50% over the required quantity does no harm; for the reason that the salt is quickly oxidized in the water to sodium sulphate, which cannot be tasted in such low concentrations. For one million gallons of water Traube recommended 35.7 pounds of chlorinated lime and 16.8 pounds of sodium sulphite. The quantity of chlorinated lime applied may seem abnormally high in the light of more recent observations and experiences in this country, but it explains why the early observers were forced to look for means to remove the repugnant aftertaste in water thus overdosed. The need for remedial measures grew still more pronounced when later observers were led by laboratory tests to employ still larger quantities of chlorine in the form of chlorinated lime or sodium hypochlorite. Sickenberger and Kaufmann disinfected the turbid Nile water at Cairo with sodium hypochlorite equivalent to 2 mg. of available chlorine per liter, which corresponds to about 50 pounds of chlorinated lime per million gallons of water. Bassenge recommended for disinfection on a large scale the enormous quantities of 2,445 pounds of chlorinated lime for a ten-minute contact period down to 270 pounds of chlorinated lime for two hours' contact. To eliminate the taste a quantity of calcium bisulphite, $Ca(HSO_3)_2$, somewhat larger than the quantity of chlorinated lime employed had to be added. Bassenge decided on the use of calcium bisulphite for the neutralization of the excess of chlorine with the advice of Dr. B. Proskauer. Calcium bisulphite is a saturated solution of calcium sulphite in sulphurous acid. It has the strong odor of that acid. On standing it decomposes, forming calcium sulphite and water. The reason Bassenge did not make use of sodium sulphite as did Traube, was that it forms sodium sulphite in sufficiently large quantities to have a marked therapeutic effect which would not be the case with calcium bisulphite. An additional reason was that the free acid present would more readily combine with the chlorine than would the neutral sulphite. No definite quantity of bisulphite was recommended since it rapidly changes on storage. The quantity had to be determined each time by actual trial. Lode likewise used excessive quantities of chlorinated lime and advised the use of either sodium or calcium sulphite for the neutralization of the chlorine after 5 to 10 minutes' contact. Later he went quite thoroughly into the question of removing the taste by various chemicals, of which he preferred the neutral sodium sulphite, but also recommended for disinfection quantities of chlorinated lime as high as 1,250 pounds per million gallons of water.

It is also interesting to note in connection with the early disinfection experiments, that acids were brought into con-

tact with the water after the chlorinated lime has been added, in order to liberate the active chlorine which otherwise would not enter into the reaction. Lode adds for each pound of chlorinated lime about 1.2 pounds of concentrated hydrochlorite acid. Citric acid likewise has been used in quantities of approximately 15 grains per gallon of chlorinated water for the same purpose. It is said that the taste was not influenced by the addition of the citric acid.

From the foregoing it must be apparent that even if the taste was effectively removed by the addition of various chemicals, the treatment of water supplies at that time must have proven too expensive to be considered anything more than a temporary relief measure in times of epidemics. As such the Traube-Lode process was employed during a typhoid epidemic at the Austrian city, Pola, in the fall of 1896 and the winter of 1896-97, by Dr. Meerans on the recommendation of V. Kusy. A total of 450,000 gallons of treated water was supplied during that period and sodium thiosulphate ($Na_2S_2O_3.5H_2O$) served for the elimination of the taste. The consumers became eventually used to the water in spite of its high turbidity resulting from the chlorinated lime treatment. Lode criticized the use of sodium hyposulphite in Pola and assumed that it had been used by mistake, since in his earlier writings, he called the sodium sulphite "Antichlor," which as a matter of fact is the trade name for sodium thiosulphate.

The uncertainty of the quantity of chlorinated lime to be added to different waters and the almost general introduction of safer ground water supplies led the Germans to abandon altogether this treatment as a permanent procedure.

There are, however, industrial regions in Germany where similar conditions exist in regard to water supplies as in this country, which have caused renewed interest in the hypochlorite treatment. Such conditions are met with in the coal mining region of the Ruhr watershed and the disinfection of more than a dozen waterworks supplies carried on by H. Bruns with quantities somewhat smaller than those originally employed by Traube, gave with two exceptions very satisfactory results. The quantities of chlorinated lime varied between 12.5 and 25 pounds, (containing approximately 33% of available chlorine) per million gallons. While complaints were frequent when the treated water was used by the consumers, the complaints ceased as soon as sodium thiosulphate was added as a routine measure. The compound was added 15 to 30 minutes after disinfection in quantities equivalent to 50 to 70% of the weight of the chlorinated lime. As spoken of above, the disinfection was a failure in two cases. In one case the organic contents of the water expressed as "oxygen consumed" reached as high as 30 p.p.m. and in the other case the water contained 2 p.p.m. of iron.

The good results obtained on adding taste removing chemicals induced us to believe that like results could be obtained in our "hypo" plants where the amount of chlorinated lime approaches the limit of recognizable taste. In some of our own observations we found that 0.6 p.p.m. of available chlorine (equivalent to 15 pounds of chlorinated lime per million gallons) was about the smallest quantity which could be readily tasted but it is a fact that even smaller quantities are discerned by sensitive non-smoking consumers, particularly when the temperature of the water is high. We should remember that in plants where smaller quantities, such as 6 to 8 pounds of chlorinated lime per million gallons, are employed, accidental overdosing followed by a flood of complaints, is frequent. W. H. Dittoe and R. F. MacDowell, in reporting on the result of an inquiry among a large number of cities in United States and Canada, in which "Hypo" treatment is installed, state that a taste is not often noticed when chlorinated lime is applied in quantities of 7 pounds per million gallons or less, but that there is often complaint on using larger quantities. However, with certain waters even smaller quantities may produce tastes and odors. It would then seem an advantage to apply a "sure cure" remedy if this can be done without materially influencing the cost of the treatment. Our tests have been made on Lake Michigan water and, while the relation of the chlorine to the chemicals applied theoretically remains the same, it is possible that the actual quantities would require adjustment with different water supplies.

We know that storage of chlorinated waters by itself is a simple method by which to rid the water of the taste, depending on the time allowed for this purpose. The chlorine taste in lake water treated with 12.5 pounds per million gallons disappeared, at room temperature, in a little over 3 hours. Simple aeration will hasten the disappearance, reducing the time to something like 2 hours with the same quantity of bleach. The amount of air applied was 0.3 cubic feet per gallon of water. It may also be stated here that the elimination of the taste coincides well with the disappearance of the potassium iodide-starch reaction. There is no definite chemical reaction taking place on aeration which would account for the speedier elimination of the taste; the chlorine seems to be carried off by the air bubbles passing through the liquid. On a large scale a prolonged storage period or storage with additional aeration would be in most cases not a practicable procedure.

Contact of chlorinated water with wood charcoal will quickly do away with the chlorine taste but the water in our experiments absorbed certain ingredients from the charcoal which, by themselves, resulted in a pronounced taste. Whether other carbonaceous material will give like results we do not know, but it is probable that sedimentation or filtration would be subsequently required to rid the water of the matter in suspension.

The chemicals which seem of value for the purpose of removing the chlorine taste from waters are sodium sulphite and sodium thiosulphate, both of which are strong reducing agents and form tasteless compounds when brought into contact with chlorine. The calcium sulphite and calcium bisulphite which have been employed by some early observers have not been utilized by us for the reason that they are not readily obtainable and too expensive for practical application even when bought in bulk. The calcium sulphite, $CaSO_3.2H_2O$, is only sparingly soluble in water; the calcium bisulphite, $Ca(HSO_3)_2$, is very unstable on account of the presence of free sulphurous acid and it is not a commercial preparation. When coming into contact with chlorinated lime the reaction is analogous to the one taking place with sodium sulphite:—

$$CaSO_3 + CaOCl_2 = CaSO_4 + CaCI_2$$
$$Na_2SO_3 + CaOCl_2 = Na_2SO_4 + CaCl_2$$

Our experiments on the neutralization with sodium sulphite were made on late water treated with chlorinated lime as well as free freshly generated chlorine and practical tests coincided well with the theoretical quantities of chemical as determined by calculation. For 0.01569 gm. of bleach containing approximately 33% of available chlorine 0.01815 gm. of crystalline sodium sulphite were required, or 1.2 pounds of sulphite for each pound of chlorinated lime. When free chlorine is employed the reaction taking place is:

$$Na_2SO_3 + 7\ H_2O + Cl_2 = 2HCl + Na_2SO_4 + 6H_2O$$

One pound of liquid 100% chlorine would necessitate the addition of approximately 3.6 pounds of crystalline sodium

sulphite for neutralization. An important point to keep in mind is that it takes as much sulphite for the free chlorine as for the total available chlorine in chlorinated lime to remove the taste of treated waters. The reaction between the sulphite and the chlorine takes place instantaneously, thus removing the taste as well as the odor at the same time. No harm can be done with a reasonable overdose since the sulphite could not be detected in such low concentrations. Furthermore, it would take but a very short time for the dissolved oxygen in the water to convert the sulphites into sulphates. Medicinally the sulphites are of low toxicity and fairly strong antiseptics on account of their ability to withdraw oxygen from organic matter, but they are rarely used nowadays for that purpose. The average medicinal dose is 15 grains. Supposing we overdose a treated water containing 10 pounds of chlorinated lime per million gallons with 50% of the quantity of sulphite required, which would be an excess of 6 pounds, one would have to drink about 370 gallons of the water to get a single medicinal dose, not considering any oxidation into sulphates at all. Since the medical dose of sodium sulphate, which is formed in the reaction, is 240 grains, its therapeutic effect is surely negligible. The wholesale price of crystalline sodium sulphite is approximately 4 cents per pound when bought in 100 pound lots. This would add about 125% to the cost of the chlorinated lime, assuming that the market price of chlorinated lime containing 33% of available chlorine is 2⅛ cents per pound. Considering the benefit to be derived in many cases from the use of the sulphite, the additional cost would not seem unreasonable. There are, however, serious drawbacks to the continued use of sodium sulphite, one of which is the fact that it deteriorates readily, forming sulphates, which of course are completely inert as far as the taste-removing property is concerned. Weak solutions in particular will change from day to day. We have noted N/40 sodium sulphite solutions to weaken over 50% in less than a day. The aqueous solution of the sulphite is neutral or feebly alkaline and has a cooling, saline, sulphurous taste.

The sodium thiosulphate, $Na_2S_2O_3.5H_2O$, as first applied in Pola and recently recommended by Burns, has striking advantages over the sodium sulphite. It is commercially used very extensively as "Antichlor." When sodium sulphite comes into contact with chlorine the reaction taking place is the same as with iodine. With thiosulphate the oxidation is more complete, and this therefore alters materially the proportions of chlorinated lime and thiosulphate necessary to do away with the taste and odor. The reaction is as follows:

$$Na_2S_2O_3 + 8Cl + 5H_2O = Na_2SO_4 + H_2SO_4 + 8HCl$$

The acids formed in the neutralization process immediately combine with bases to form neutral salts. Lode stated that in his experiments he found it impossible to establish quantitatively corresponding values of chlorine and thiosulphate, and he recommended 0.8 to 0.9 of the quantity of chlorinated lime for the purpose of taste removal. Bruns recommends values of 50% to 70% of the quantity of chlorinated lime applied. As a matter of fact, it seemed impossible in our experiments to obtain checks when a chlorinated lime solution was titrated with a thiosulphate solution under addition of potassium iodide and starch in the absence of acid. Of course, when acid was added and all of the available chlorine became liberated, checks were readily obtainable. This was likewise the case when the same definite quantity of potassium iodide was added, each time without acid, and the solution immediately titrated. We have found, however, that the theoretical quantity of thiosulphate necessary to complete the reaction and remove the taste as well as odor coincide always with the amount necessary to satisfy the total available chlorine in the chlorinated lime employed. For one pound of chlorinated lime containing approximately 33% of available chlorine, the theoretical quantity would be 0.28 pounds of crystalline thiosulphate, or approximately 30% of the weight of the chlorinated lime. One need not be afraid to add an excess, since even 100 pounds of thiosulphate in one million gallons of pure water cannot be tasted. As a matter of fact, we should strongly recommend the application of thiosulphate in quantities of one-half of the quantity of the chlorinated lime to be on the safe side at all times and to take care of all reasonable overdosing with chlorine.

The commercial sodium thiosulphate is about 98% pure; it is a colorless, odorless salt possessing a cooling taste, afterwards bitter. It is very stable in air below 92° F., but loses moisture above that temperature. It greatly exceeds the chlorinated lime in stability. The salt is readily soluble in water and neutral or faintly alkaline in reaction. The medical dose of thiosulphate is the same as that of the sodium sulphite. Formerly it has been used to a limited extent as a weak antiseptic. The price of the commercial preparation is about 1.85 cents per pound when bought in 100 pound lots; it is therefore cheaper than chlorinated lime.

To summarize the advantages of the sodium thiosulphate over the sodium sulphite, we would say that it is much more stable, much cheaper, and that it requires less in actual weight to accomplish the same result. The combined cost of the treatment is within easy reach of a community, since it adds but 40% to the cost of the chlorinated lime, and the advantage of its application will best be appreciated in places where taste troubles are frequent. Even when less than the theoretical quantity of thiosulphate is added, it is bound to lessen the frequency of complaints. A very important point to keep in mind when such treatment is resorted to is that the thiosulphate stops the germicidal action of chlorine the moment it comes into contact with the treated water. This is not of serious consequences, however, since we know positively that the destruction of bacteria by the chlorine is extremely rapid and in most cases practically completed in the first five minutes. We should recommend, however, at least 10 to 15 minutes as a safe margin, or even more when conditions warrant. When the chlorinated water is stored, the simple addition of the thiosulphate in solution will suffice, care only being required to obtain a fair distribution. There is not much chance for the thiosulphate to unite with substances other than chlorine, since those compounds have a pronounced chemical affinity. Where the treated water is directly discharged into the mains, without previous storage, provisions will have to be made to dose the treated water continuously with thiosulphate at a point where disinfection has been practically completed. The thiosulphate does not attack metals, and therefore would not cause trouble in the dosing chamber, as does the chlorine. Where quantities like 2 to 5 pounds of chlorinated lime are applied and the dosing can be made reasonably automatic, the application of thiosulphate will hardly seem necessary. However, where larger quantities are required and taste troubles ensue, our observations would lead us to recommend the application of sodium thiosulphate as a permanent procedure.

Argentina owes a great part of her present prosperity to the excellence and extent of her railways, and in this connection a tribute is due to the courage and persistence of British railway men and investors, who were the pioneers of construction. As more and more the necessities and advantages of railways are being realized, so it may be expected that development will be even more rapid in the future than it has been in recent years.

TO RAISE THE LEVEL OF LAKE ERIE.

Canada and the United States are equally interested in the recent finding of the International Waterways Commission as a result of its investigation into the possibilities of raising the level of the water in the upper Niagara River and Lake Erie. The problem has been under the Commission's examination for a number of years, and the recent recommendation is but one of a number of suggestions towards its solution.

Briefly, the International Waterways Commission, a body representative of both countries, has just recommended to their respective governments, the building of a submerged weir in the Niagara River at Hog Island, just above the Welland River, on the Canadian side, to extend toward the New York shore to a point opposite Gill Creek. If carried out, the restriction to flow will raise the level of the upper waters of the Niagara through a height of three feet for a distance of approximately one and a half miles. The effect opposite Buffalo would be an increased level at low water of 1.08 feet, and at flood of .19 feet. The level of Lake Erie would be raised .31 feet at low, .39 feet at mean, and .11 feet at extreme flood levels. Extending into the upper lakes, the mean level of Lake St. Clair would be influenced to an extent of .23 feet increase, and that of Lake Huron by .09 feet. The cost of the weir, including the levees necessary to protect adjoining shore properties, is estimated at $3,500,000.

Of particular importance, as it would be to the towns and cities on Lake Erie, whose docks and harbors will be rendered more usable, and whose water transportation facilities will thus be considerably enhanced, the proposed dam would have no appreciable effect, it is claimed, upon the waters below it. Lake Ontario and the St. Lawrence would not suffer from any perceptible decrease in flow from the Niagara. The only precaution necessary, below the weir, would be the construction of a guard-lock in the barge canal at Tonawanda, N.Y., to remedy the effect the new weir would have upon its level.

The Commission pointed out that the weir would be of further value in eliminating any injurious effect upon the level of Lake Erie, due to the diversion of water at Niagara Falls for the generation of hydro-electric power, and also that it would reduce the degree of variation in the Lake Erie water level by four and a half per cent.

Several years ago the Commission submitted a report on the advisability of constructing an ordinary dam across the Niagara for the purpose of controlling the Lake Erie level. The scheme did not meet with favor, the Commission considering as too great the possibility of consequent damage to property below the dam, and, although the present recommendation aims at only partial control, the disadvantageous possibility of detriment to property is largely eliminated. Surveys had also been made for a proposed site immediately below the mouth of the Welland River, but the probability of resulting floods from a weir built at that point defeated any advantages the location presented.

In connection with this scheme, it is of interest to recall the suggestions made some years ago by the United States War Department, that a weir be built along the crest of the Falls, having for its purpose the distribution of flow over the brink, and resulting, it was predicted, in increased grandeur of appearance. According to the report, however, this would have had no effect upon the level of the water in Lake Erie.

THE ENGINEER AND THE LANGUAGE.

In an address delivered in 1909 to one of the university engineering societies in the United States, Mr. Onward Bates, C.E., then the president of the American Society of Civil Engineers, states that engineers' opinions should be expressed with a regard for accuracy equal to that used in their mathematical computations, and that precision in written and spoken expressions of fact and opinion is most essential in a profession that is so exacting in its nature as that of engineering. Just how far the average engineer's command of the English language falls short of such accomplishment has its solution in the frequently aired criticism that engineering is a narrow and extremely one-sided profession. The engineer is prone to leave to the followers of other professions the copious use of language. Other people do the talking while he works—the drawing up of contracts and the writing of specifications and reports are the literary works of the average practising engineer. It is true that in these examples of literary ability one does not always find clear and distinct thoughts and correct representations. Serious complications frequently arise as a result of the derivation of divers meanings from expressions failing to convey a simple idea. This is a practical example, showing that the criticism is not without foundation.

Justly considered, the engineering profession is not inferior to the legal, ministerial, or medical professions, but, compared with them, it has a remarkably small amount of necessary writing associated with it. To this fact is attributable the impression among engineers that the careful attainment of facility of language is not as necessary in his profession as in the others. Experience has taught severe lessons in a manner mentioned above, in dislodging this erroneous idea.

Accuracy in engineering demands accuracy of expression, and has a severe handicap in lack of facility of language. According to Mr. Bates, and others, this shortcoming, and it is quite general among engineers, has its rising at the universities, from which men graduate insufficiently equipped in the matter of knowledge of the English language, a most important requirement. In these days of specialties in technical courses, one cannot expect to master all, and to the student, as to the instructor, the essentials of mathematics, the use of engineering instruments, and the general principles upon which engineering is based, leave little or no time for studying English. A man thus graduates with a university degree backed by a preparatory school certificate in English, which is not enough. It only requires such an address as that of Professor Swain, appearing in this and the last issue of *The Canadian Engineer*, to illustrate how important an instrument in the hand of the practical engineer is a thorough knowledge of language. Be a man's training what it will, in the literature at his disposal, and in the writing, for the benefit of others, of his own ideas, the engineer of to-day need anticipate no better opportunity for elevating himself in his profession, than by adding to his equipment, more of this necessary part.

One thing is certain, an engineer of all men requires such knowledge of the technique of the language that he can use it with accuracy and facility at all times. The bad construction of a sentence or the erroneous use of a word may result in costly litigation and heavy loss; therefore, the language merits far more study than the best technical courses provide.

EDITORIAL COMMENT.

The recent awards by the Hydro-Electric Power Commission of Ontario of contracts in connection with the construction and equipment of a hydro-electric power plant at Wasdell's Falls, on the Severn River, denotes an important event in the history of the Commission. The opening of the headgates of this power plant should be observed with ceremony, as it is an epoch-making event, announcing the entrance of Ontario into a period of extensive generation of hydro-electric power from its many inland waters, and the accompanying distribution of it throughout the Province by the Hydro-Electric Power Commission. It is likely that the plant at Wasdell's Falls will be followed closely by several others, and that at the close of present season plants will be in operation.

* * * *

The Canadian Pacific Railway Company will electrify a section of their line in the mountain division, it is announced, and if the results obtained warrant it, the electrification of many of their mountain branch lines will follow. The replacement of steam locomotives by electric tractive power, even in this small degree, marks a new period in Canadian transportation development. When the Canadian Pacific will realize, by this innovation between Rossland and Castlegar, the advantages of electricity over steam for mountainous traffic, other electrification units will follow in rapid succession. A 2,400 volt, direct current, trolley-system is the service that has been decided upon for the new project.

* * * *

In his report to the Minister of Lands, Forests and Mines, Ontario, Roads Commissioner J. F. Whitson recommends an expenditure of $1,000,000 in the construction in main and trunk roads and in the improvement of existing roads in the districts of Northern Ontario. The report, which covers the work accomplished in 1912, contains information concerning the construction of some thirty roads up to the end of the season in November. A statement of the expenditure on this road construction in Northern Ontario, which is carried on under the Northern Development Branch of the Department of Lands, Forests and Mines, is as follows:—

Wages of Workmen		$112,155 76
Amount paid on road construction under contract		32,633 64
Salaries of office staff, including assistant engineers and inspectors		7,726 48
Camp equipment—tools, implements, road machinery, tents, blankets, utensils, etc.		13,035 90
Supplies, provisions, freight and express charges, etc.		39,594 35
Insurance on warehouse and contents, Cochrane		380 00
Office expenses—		
Stationery and printing	$269 35	
Travelling, railway and hotel expenses	986 64	
Postage and telegrams	97 48	
Furniture, rent of offices, equipment and incidental expenses	897 31	
		2,250 78
Medical and surgical expenses for workmen		248 05
Other expenses, made up of small accounts, livery, etc.		421 35
		$208,446 31

THE ENGINEER AND THE SOCIAL PROBLEMS

THEY ARE WITHIN HIS PROVINCE — HIS CAPABILITIES FOR SOLVING THEM—THE POSSESSION OF CONSERVATISM AN ESSENTIAL SAFEGUARD — MORE RECOGNITION FOR EXPERIENCE, KNOWLEDGE AND SPECIALIZED TRAINING

By DR. GEORGE FILLMORE SWAIN, Pres. Am. Soc. C.E.

(Continued from last issue.)

[NOTE.—As stated at the beginning of this article in the issue of June 26th, *The Canadian Engineer* is preparing a forty-page pamphlet containing the entire address of Prof. Swain. A limited supply of them will be ready in a few days and will be mailed upon request.—ED.]

TWO of the most important requisites for authority in matters of opinion, seem to be a spirit of conservatism, and the possession of good judgment. The man who is slow to advocate a change, who adheres instinctively to old ideas and practices until there is reasonable ground for the belief that a change will be beneficial, is clearly a safer guide than he who rushes into all sorts of new schemes and is ever ready to throw aside the results of years, because perfection has not been attained. Conservatism is the brake which prevents our rushing to destruction. The possession of grasp and of good judgment is also essential. By these are meant the ability to see all the elements entering into a problem and to see them in their proper proportion. The narrow-minded man does not see all the elements in a problem; such a man lacks grasp. The unbalanced man, while he may see all the elements, exaggerates some and minimizes others; such a man has poor judgment. The advice of either is unreliable.

It is worthy of fuller inquiry what the reasons are, reduced to their elements, which cause men to differ in their opinions. Take almost any subject, except one dealing with abstract relations, and opinions may be cited which are diametrically opposite. Take such a subject, for instance, as the relation of forests to stream flow. Here we have a scientific subject, regarding which it might be supposed that experiments or observations might be made, scientific principles applied, and opinions reached which would be agreed upon by all intelligent men conversant with the subject. And yet, on this subject, and still more so on even more speculative subjects, men of equal authority or experience will be found holding diametrically opposite views. Why is it?

It seems to me that if intelligent men differ on any subject, it must be due to one or more of the following causes:

1. One or the other is not in possession of all the facts or principles involved.
2. One of the other may use facts or principles which are incorrect
3. One or the other may reason incorrectly.
4. One or the other may see the facts out of proportion, attributing too great importance to some and too little to others.
5. One or the other may illustrate the natural stubbornness or imperviousness of the human mind.

It is not always clearly recognized that facts cannot always be compared directly, because they cannot be expressed except in incommensurable terms. For instance, if we ask which is the greater, six feet or two meters, there will be no disagreement in the answer; but if we ask which is the more important, 10 feet or $5, or which is more important, truthfulness of beef steak, the reply is not entirely obvious. These are not fanciful illustrations. We are continually obliged to make comparisons between things which have to do with our physical well-being and those which have to do with our moral or spiritual well-being. They are incommensurable, yet they must be compared and an opinion formed from the comparison. In planning a railroad station, for instance, a certain design requires the passengers to walk a certain number of feet, while another design costs more but requires less walking. Here is a comparison which must be made between feet and dollars. In such a case, some will endeavor to express the comparison in commensurable terms. They will compute, perhaps, the value of the shoe leather that would be saved in a year if all the passengers using the station have to walk the given distance less, and compare it with the interest on the additional expenditure. Similarly, the expenditure of millions of dollars is asked for electrification, the advantage urged being the saving of a certain number of minutes each day for each passenger and because the aggregate saving of time in a year, valued at the average annual wage of an individual, amounts to a sum greater than the interest on the cost. Such comparisons are generally made by those who find their judgment unable to deal with the subject in any other way, who cannot compare except by measuring or weighing, as they have been trained or accustomed to do. Yet, such persons do not realize that the comparisons they make may be entirely deceptive. Although more rapid transit may render a journey quicker, it does not follow that the time is saved. It may be usefully employed in reading, or in conversation, or in sleep, or in meditation. An additional fifteen minutes spent in going from one's house to one's office, is not necessarily lost; it may be utilized like any other fifteen minutes in the day. Even if spent solely in meditation, it would be most beneficial, for, as Arnold Bennett says, the great defect of the age is the absence of meditation. In such arguments as that for electrification the mistake is also made of not considering whether the individuals who would make the saving claimed are the same individuals who would bear the increased cost.

Referring to the classification above, it is evident that an ability to observe correctly, the faculty of getting at all the facts, and of knowing when all the pertinent facts have been collected, the ability to reason from those facts, the possession of conservatism, the absence of stubborn persistence in holding a previously formed opinion in the face of proof of its error, and, above all, the faculty of seeing things in proper proportion, or good judgment, are essential in forming an authoritative opinion.

How can the absence of these qualities be detected? To discuss this would lead us too far, but there are one or two points to which I wish to refer. For one thing, dogmatism, or intellectual arrogance, in speculative or uncertain matters, is an almost certain indication of disqualification. The man who in such matters shows intolerance of opinion, may generally be disregarded. He who in matters of opinion is cocksure, who terms all men who disagree with him knaves or fools, who resorts to epithets and extreme statements, who asserts that all honest men should believe as he does, or who

makes similar assertions, is either wilfully trying to mislead, or is unworthy of credence. This is a fault which is observable particularly in the immature, whether old or young in years.

If, therefore, we find an author proposing changes in political or social conditions, who, referring to eminent men at least as honest and intelligent as himself, and more learned and experienced than he is, in terms of disrespect, we may be pardoned if we surmise that the temper and judgment of the author are not such as to entitle his words to be received with authority. So, also, if we detect what we believe to be frequent gross errors in reasoning, or a temperamental lack of the power to see things in what is clearly their proper perspective, we may save ourselves the trouble of pursuing such an author farther, even though his sentences are adorned with flowers of rhetoric or by Biblical quotations.

The Disregard of Experience.—One of the most serious tendencies of the present day, particularly in the United States, a tendency which, like the disregard of authority, seems to result from that to regard men as equal, is the disregard for experience. It is a tendency fraught with great possibilities for evil, which must be recognized by every serious thinker.

In any occupation, except those which have to do with the study of purely abstract relations, which, as above explained, may be arrived at correctly in the seclusion of the study, it is almost self-evident that experience is of great value. In any occupations having to do with pure and applied science, and particularly in those having to do with man and his relations to society—that is to say in politics, economics and government, as well as in engineering—experience is a necessary qualification for arriving at correct judgments. A person having a power of perception of mathematical relations may become a profound mathematician at an early age; indeed, the perception of mathematical truths is essentially a subjective faculty, and may be most correct and powerful when the mind is removed from the objective state. Some mathematical prodigies have reached their greatest power when mere boys, and have lost it with increasing age and contact with the objective world. But, in business affairs, no amount of reading of books or of closet meditation can take the place of actual experience. But, if all men are equal, then the boy's opinion is as good as the man's, and experience is a mere useless drag.

It seems to be an inherent tendency of our form of government, to disregard the value of experience; any man is considered good for any job; all he has to do is to get the votes, by one means or another. Men who have made little or no study of government, and who have had no experience in it, are considered capable of judging of and administering laws and of occupying any elective or appointive position. The butcher, the baker, the candlestick maker, are all eligible for the state legislature, for congress, for the senate, for the mayoralty, or the presidency. This condition necessarily results in gross inefficiency and waste, not always through evil intent, but perhaps more often through stubbornness, ignorance, conceit, or the unwillingness or inability to select and take good advice. We talk much of graft and rightly condemn it. But, as Lecky has pointed out, corrupt governments are not necessarily extravagant. Graft is injurious mainly to those who practice it. Inefficiency and inexperience are much worse for society in general; and laws which hamper industry, which harass property, or which—through unwise taxation, or extravagant state expenditures for the benefit of particular classes—plunder large portions of the community, are much more injurious to the general good than the pilfering of a few thousands of dollars a year. Sir Henry Maine remarks that the form of bribery which is most to be feared in a democracy, is that of "legislating away the property of one class, and transferring it to another."

Only in one department do we recognize experience, knowledge and specialized training as necessary, and that department is the administration of justice. No one but a trained lawyer is considered eligible for the position of judge, and in most instances, judges are appointed and not elected, and are, therefore, not driven to seek the votes of the mob, or subject to popular whim, or the arts of the demagogue. For this reason, our courts have been rightly deemed the safeguard of our liberties. Not until our legislators and our administrators of public affairs are chosen from men trained and experienced, and who have ascended from the bottom step by step, will efficiency, economy and wisdom be attained in our government. Whether this time will ever be reached may well be doubted. We are much less advanced in this respect than some of the countries in Europe, where the expert is more recognized and has a higher standing, and where knowledge, and particularly experience, are valued higher than here. If financial measures are under consideration, men experienced in finance should be sought and their advice followed. In our country, experience in finance seems to be to-day looked upon as a disqualification for giving sound financial advice, and the same in railway and other affairs. Under such conditions, satisfactory results cannot be attained. Either, as a people, we are more dishonest or more unwise than the people of Europe.

In these days, when higher education is a fad, there is an increasing tendency, in my opinion very pernicious, to regard book knowledge as the equivalent of experience. We are more and more inclined to regard those as able to speak with authority, whose knowledge is derived simply from books, who perhaps have spent their lives in a professorial chair, with no actual experience in the subjects they teach or write about. We shall in time learn the fallacy and danger of this; but, in my opinion, at the present time great harm is being done by talking too seriously, in questions of politics, government, economics, finance and business, and sometimes in engineering, the opinions of theoretical men and closet reformers, whose advice we would not think of following in the conduct of our own private affairs. Some of these men will come within the class of those who, to use the phrase of Mr. E. P. Ripley, president of the A. T. & S. F. Railroad, have "zeal without knowledge, and enthusiasm without sanity."

Of course, it must not be supposed that experience is everything. In some cases, experience only confirms a man in rule-of-thumb practice, works him deeper and deeper into a rut, and destroys his power of vision. Probably all of us have seen instances of men, whose long experience in doing a particular thing in a partcular way has only destroyed their power to see that there is another and a better way, and whose only reason for doing that thing in that way is that they have always done it in that way. Such men, however, would never, under any circumstances, be leaders. They are the soldiers in the ranks, whose only function should be to obey orders. It not infrequently happens, in the administration of some business affair, that a new man with a fresh mind, without experience in that line, but with a power of selecting good advisers, of grasping a new situation quickly, of seeing all the elements involved and of judging them correctly, will arrive at a truer decision than another man of less grasp and judgment, though experienced in the matter in question. This, however, is no argument against experience, but simply illustrates that experience must be combined with grasp and judgment: for the new man, before he becomes really proficient, must either gain his experience, or must be able to select his advisers well and to rely on them.

Not only is experience discredited to-day, but we actually find inexperience put forward as a virtue by men who should know better. One candidate for an important elective office, in an address to the electors just previous to the election, urged his qualification for election, on the ground that he had had no business experience which would prejudice his judgment in the matters which would come before him. Is not this a serious disqualification—an admission that his temperament is such that experience would prejudice him, and not teach him? Do we not want men in office experienced in the affairs they are to deal with, but fair-minded and of good judgment, whose experience, instead of warping their judgment, aids and matures it? Woe be to us as a nation when we place inexperienced men in office for fear that experience would warp their judgment.

It is, nevertheless, true that men differ greatly in the amount of experience which they need in order to perfect their powers. This will depend upon the rapidity with which they can assimilate it, and the philosophical character of their minds. It has been said that the wisest man is he who can do with the least experience; that is to say, the one who does not need to have an experience repeated again and again before he learns the lesson which it teaches, but who only needs one experience to learn its lesson, and who can extend that lesson to cover other possible experiences, thus rendering the latter unnecessary.

When we are asked, therefore, to believe and advocate any proposed policies, let us train ourselves to apply certain touch-stones before we commit ourselves. If the subject is one within our experience, knowledge and reasoning powers let us endeavor earnestly to think the matter out for ourselves and arrive at our own conclusions. In the many cases in which we cannot do this, let us carefully scrutinize the policies and their proposers, to determine how much credence we can give. Let us observe whether the author asserts them dogmatically or modestly; let us note whether he makes assertions without proof, and by incessant repetition endeavors to make us believe that assertion constitutes demonstration; let us ask whether he speaks from experience or simply from book knowledge; let us remember that he is not free from the frailties of human nature, and let us, therefore, inquire whether he has any personal interest at stake; let us assume an attitude of doubt and distrust toward all human opinions until that doubt and distrust are effectually removed. It is said that it is better to be deceived than to distrust; but, after we have been deceived, we shall be more inclined to reverse this saying, and to consider that, in the reversed form, it will be, upon the whole, safer and more conducive to our happiness. Let us be on our guard against assuming that good intentions are a guarantee of authority, and when we find ourselves in danger of being influenced by flowers of rhetoric, let us remember that "no man is more dangerous in a state than he who possesses in an eminent degree the power of moving, dazzling and fascinating his contemporaries, while in soundness of judgment he ranks considerably below the average of educated men"; and let us further bear in mind that "an excessive love and admiration of rhetoric is one of the diseases to which democratic communities are most liable."

The Tendency to Relax Discipline.—Another of the demoralizing tendencies of the equality of man is that which has led in recent years, it seems to me, to the gradual but steady relaxation of discipline. It will probably be denied by few that for the proper training and full development of the human being, discipline is necessary. Life itself is little more than discipline; it is not for pleasure; it is for work, accomplishment, development; without discipline there will be no proper development. He who is born with a golden spoon in his mouth and whose life is a continual round of pleasure, is likely to go out of the world less developed than when he entered it. "The beginning of wisdom," says Solomon, "is the desire of discipline." Work, which is itself an end, and rather to be sought than what it brings, consists largely in doing things which in themselves are uninteresting and perhaps distasteful, and we must accustom and train ourselves to be able to do this kind of work cheerfully and well. This ability will be attained only through discipline. Moreover, the man who attains a position of responsibility must be able to direct and command the work of others, and no one can command wisely until he has first learned how to obey. For this, too, discipline is necessary. Yet the tendency of recent years seems to me to have been toward a steady relaxation of the discipline imposed by law and custom upon the growing individual.

Dr. Swain then referred to the tendency toward the relaxation of discipline in educational institutions, and likewise in the application of our laws, whereby offences are condoned, and sympathy instead of sternness administered, thus encouraging a spirit of lawlessness and an unwillingness to submit to proper restraint.

The Spirit of Innovation.

Another of the tendencies very marked at the present time, is the spirit of innovation, which seems to pervade all things; whatever is, is wrong: the social custom must be changed in order to keep up with the time. This spirit is particularly observable among the young and the immature, especially if it has been preceded or accompanied by a lack of discipline in early training. It is an instance of what Ferrero terms "that youthful spirit of innovation which is in all ages the main source both of perversion and of progress." Many of our young men "all aflame with an enthusiasm unquenched as yet by any continuous contact with affairs," set out to reform the world, not so much because it needs reform as because they wish to justify their existence. This spirit of innovation is at all times a spirit to be expected and reckoned with. Every generation as it comes along, will endeavor to change the condition in which it finds itself, and will designate that change with the name of progress even though it be perversion.

This spirit of innovation which pervades all things seems to be largely a result of scientific progress; the rapid advances made in inventions of all kinds, the improvements in the arts and manufactures, have resulted in a complete revolution of the methods in many branches of industry within a comparatively few years. Men are now living who were born before there were any railroads, and almost all of us can remember the time when the applications of electricity were just beginning. An industrial plant but a few years old may be out of date and unable to compete with newer and more economical installations. We are accustomed in engineering matters to see things completely remodelled within a short time.

This familiarity with industrial change and the recognition if its benefits has naturally led to the idea that everything must be reconstructed, or it is old-fashioned and out of date, even though it be a thing in which there have been no new discoveries, warranting any change whatever; music painting, dancing, education—everything, in fact—must be completely reorganized. This willingness and desire for change affords the opportunity for unsuccessful mediocrity and for ambitious and unscrupulous failure to foist upon the public, which eagerly accepts it, forms of change which discerning men must characterize as gross, ridiculous, and demoralizing. The result, in many cases, is a deterioration pitiable to behold. Let any one compare, for instance, the

modern painting, dancing and music, with that in vogue fifty or one hundred years ago, and he will find abundant proof of this. In politics and government too, the same tendency, the same recklessness, the same demoralization, are equally observable.

Now, of course, an existing condition is not necessarily the best because it is old; neither is a proposed change advisable because it is new. In many cases, however, suggested changes, ignorantly proposed by those unacquainted with history, have been tried and have been found wanting centuries ago. History repeats itself. Nations, like individuals, will only learn by costly experience. Away with the old, make way for the new! We will not profit by the lessons of our forefathers, we must experiment and learn for ourselves. In all matters, then, let us try to cultivate the breadth of view, the tolerance of opinion, which will lead us neither to adhere to that which is old from extreme conservatism, nor to indulge in rash experiments; but let us study history, cultivate a sound and deliberate judgment, and endeavor to guide the inevitable spirit of innovation into proper channels; and let us remember, as Lecky well says, that "an appetite for organic change is one of the worst diseases that can affect a nation."

Improper Use of Wealth.

Advancing civilization and increase of wealth inevitably lead to increased luxury and extravagance; and, with our advancing civilization, this tendency is not wanting. If the experience of the past is of any value, however, it is a serious symptom of degeneration. The sudden accession of great wealth, particularly to those who are incompetent to use it wisely, engenders luxury and ostentation, and a contempt for those less fortunate; thus stimulating, to a certain extent, an attempt of the latter, particularly if endowed with the ballot, to recoup themselves and gain what they conceive to be their rights at the expense of wealth, by various forms of unjust taxation and other well-known expedients. If it is our duty to preach the gospel of content and the inequality of man, it is equally our duty to preach the proper use of wealth, and the proper attitude of the wealthy toward those less fortunate; and while believing that individual initiative should be stimulated to the utmost, and allowed to enjoy the fruits of its success, it may, nevertheless, fairly be questioned whether some of the rewards under present conditions are not too large, and whether men would not exert themselves as well for the prospect of a more reasonable recompense as for the prospect of unreasonable and excessive riches. But again history repeats itself, and things move in cycles. Peace causes prosperity, prosperity gives rise to wealth, wealth gives rise to luxury and extravagance, luxury and extravagance are the source of contention, contention results in war or social revolution, these result in poverty, poverty results in peace, and so the cycle is completed.

The Part for the Engineer.

And now you may very likely have asked what has all this to do with engineering, or with the engineering profession; what is the appropriateness of a discussion of social conditions before a society of engineers? My answer is that the engineer is primarily a member of the social body; that its problems are his problems; and that he cannot avoid the responsibility of taking a share in their solution. The problem of the twentieth century, it seems to me, will be preeminently, a social problem, and upon its solution will depend the happiness of mankind for years to come. Moreover, this social problem is largely, as I have shown, the outcome of the work of the engineer who, as the advance agent of civilization, has been the main factor in creating the conditions which give birth to this problem. It will be evident, therefore, that I differ from one of my predecessors who, in his annual address, intimated that social problems were out of the province of the engineer and that he should not meddle with them. On the other hand, I maintain that it is his duty to exert himself in their solution. Moreover, I consider this duty the more necessary because I believe the engineer to be well fitted—possibly better fitted than any one else—to solve these problems wisely. Let me briefly give you my reasons for this opinion.

The engineer is by training a scientific man. If his education is what I conceive it should be, and what it will be more and more in the future, it will consist of a training in mathematics, logic, science and in the technical branches of his profession, together with a sufficient amount of study of the humanities—history, economics, language, literature—to give him a clear view of the relations of things. He will be pre-eminently by training a scientific man, but with a power of understanding and grasping social questions. Now, a scientific training has this great virtue, that its end and aim is constantly the discovery of the truth. The truth for its own sake, independent of everything else, is the object of the scientific man and therefore of the engineer. In this respect, it is, in my opinion, the noblest as well as the most widely useful of the professions. The lawyer is not always concerned in arriving at the truth; he is too frequently tempted to make the worse appear the better reason. As one of that profession has expressed it, his object is not to get at the truth but to win cases. He is constantly under the temptation to pervert the truth, or to suppress it, if the exigencies of his case demand.

Furthermore, the engineer is exposed to a very direct personal responsibility which cannot but steady his character and increase his self-reliance and self-control. While he does not always receive the credit of his success, he cannot succeed in throwing the responsibility for his failures upon others. If a lawyer loses his case, as Mr. Choate once remarked, it is never his fault; he can always charge it to the prejudice of the judge, or the ignorance of the jury, or the untruthfulness of witnesses. He goes on and obtains new clients and new fame. If the doctor loses his patient, it is never his fault; he can always charge it to the disobedience or delay of the patient, or maintain that a cure was impossible. But if an engineer builds a structure which fails or a machine which will not work, the responsibility is his and he is held accountable.

Again, the engineer is a business man, for engineering is business and business is engineerig; he deals with men, he has to do with financial affairs, he learns the characteristics of human nature, and his training, therefore, tends to teach him tact, moderation and conservatism.

Of course, any sweeping eulogy or disparagement of any class of men cannot be truthfully made. Engineers will differ on questions of opinion, as other men will. there are dishonest, untruthful, unreliable engineers, as there are men of this type in every class. No doubt the ranks of our society include men who will widely disagree with me on the questions which I have discussed; there are men who will hold extreme views in one direction or in the other; men who will be dogmatic, intemperate in language and in thought, inaccurate in reasoning, insincere in opinion. No class of men has a monopoly of virtue or of error. Neither are these excesses confined to men of weak minds or deficient training. As Lecky says: "Strange veins of insanity and capacities for enthusiastic folly sometimes flaw the strongest brains, and the impetuous ebullitions of youth which impel some men into extravagances of vice, develop in other natures into not less wild extravagances of thought."

Nevertheless, on the whole, if there is anything in training and experience, may we not believe that engineers, as a class, have the training, temper, and experience which will best enable men to judge sanely and solve wisely the social problems which confront us?

What, then, may the engineer do to aid in the solution of the social problems of the 20th century?

In the first place, he should consider it his duty not to retire into the technical recesses of his professional work and content himself with being the servant of other men, but should actively exert himself and take the initiative in the great problems of the day. He will find that these problems in their details are largely of an engineering character.

What, for instance, is involved in the problem of administering the affairs of a great city? Do they not involve, in the main, the preservation of the health, safety, property and order of the community? and are they not, therefore, predominantly of an engineering character? Financial and legal questions of great importance are, of course, involved, but why should the engineering problems be considered secondary to these? Engineers can employ financiers and lawyers, as well as be employed by the latter. I see no reason why the position of mayor of a city could not be filled at least as satisfactorily by an engineer with proper breadth of view, training and experience, as by a man of any other profession. Yet, I doubt if the mayor of any city in the United States is or has been an engineer.

The same holds true of other administrative positions. The management of our great corporations involves problems largely of an engineering nature, and high administrative positions in these concerns are being more and more given to engineers. Even such a position as that of president of a republic is not one which the engineer should necessarily consider himself excluded from. Why is he not as well qualified to fill it as a soldier, a lawyer, or a college professor, provided his training and experience, judgment and breadth of view warrant. Two of our greatest presidents, Washington and Lincoln, while not engineers, did have some little practice in what was then termed engineering, and one president of the French Republic has been a professional government engineer.

There is perhaps a tendency to-day towards better recognizing the qualifications of the engineer in the administration of municipalities and larger political units. The position of commissioner of public works in a city is perhaps the most important municipal position next to that of mayor. Formerly, this position was monopolized in most cities by men who were mere politicians. Nowadays, it is quite common to appoint engineers to such posts. In Boston, Philadelphia, Cincinnati, and very likely other cities, these positions are now held by trained and educated engineers, and this recognition I consider significant and deserved. Engineers, however, will not and should not be recognized in this way unless they show their interest in public questions, unless they inform themselves about them, unless they study the economic and social, as well as the engineering problems involved, and unless they assert themselves before the public. This, I trust, they will do more and more as years go by. "The fault, dear Brutus, is not in our stars, but in ourselves, that we are underlings."

A question which is much before us at the present day is that of conservation. Conservation, as I understand it, consists in a wise economy and proper use of the materials and resources that are afforded us by Nature. It is essentially the avoidance of waste; it does not mean that natural resources shall be withdrawn from use, but that they shall be used wisely and economically. It does not mean that the present generation shall suffer for the benefit of future generations, but that the present generation shall not [illegible] generations. Now, the technical problem of the avoidance of waste and the proper use of natural resources, is a problem already solved. Applied scientists can tell just what to do and how to do it. They know how to utilize the power of falling water and how to transmit it; they know how to utilize coal most economically, they know how to utilize forest products without waste, how to prevent the erosion of the soil, how to conserve health. The unsolved problem of conservation—the problem which now concerns us most—is not an engineering problem, but a social one. It is to alter the public state of mind, to make people thrifty and economical instead of extravagant and wasteful. It is thus an attitude of mind that we have to deal with. If the attitude of mind of the public toward this problem could be made the correct one, if the individual man could be made thrifty, frugal, careful, thoughtful of the future, the problem of conservation would be solved. Why should not applied scientists, who know how to solve the problem technically, lead in educating the people to perceive the necessity for its solution? Should not mere self-interest, not to speak of public spirit, prompt us to do this? In education, too, where, as I view it, the tendencies I have referred to are plainly evident, we may as a profession exert a good influence. I have often expressed the opinion that an engineering education is the best possible education for any vocation, because it combines, or should combine in the best proportions, the study of abstract relations with that of natural science and of the humanities. These, combined with training and experience in the profession itself, should make the engineer as well educated as any class of men. He should be sane and sensible, not likely to be carried away by fallacious economic theories; conservative, and yet safely progressive. Engineers should, I think, exert more influence than they do in education, by actively interesting themselves in it, serving on school committees, and insisting on the maintenance of rigorous discipline and the scientific method. Above all, they should aid in maintaining the standard of engineering education, and prevent it from succumbing to the prevailing tendency to relaxation of discipline. The best students do not really seek such relaxation, and schools which make students work hard and which insist on a high standard of accomplishment, will attract strong men. The tendency of the times shows this, and proves that one movement to-day is towards utilitarian and vocational training. Some of the tendencies I have referred to may be in large measure only surface currents, and a strong undercurrent may perhaps be generated in another direction if the proper means are employed. This is indicated by the growth of the engineering department of our state universities within the last thirty years, and by the surprising development of such a school as the Massachusetts Institute of Technology from its first small beginnings to its position of recognized leadership in less than a third of a century. Let us make the engineering schools the place of refuge for those who are disgusted with the relaxation of discipline which prevails so largely elsewhere.

Finally, let us inquire what this society, representing the engineering profession, may do in the directions which have been suggested. We have been criticized in the past as being inactive, as taking no part as a society in the large public questions. I must frankly confess that the criticism has seemed to me in some measure deserved. Our society is large, rich, influential, but we have been too content to sit down in dignified ease, taking little or no initiative, and allowing other and younger societies to outstrip us in actual work performed and in real influence exercised. We have had some committees which have done good work in unifying practice in relation to technical matters. In these respects, however, we

have been far surpassed by two or three of the newer societies, whose committees after long and conscientious labor, have exercised far greater influence that we have in the solution of even professional problems. It is true that this is largely due to the fact that those societies are more specialized than ours, that they are composed of men all engaged in one line of work, who could co-operate and lay down the results of experiment, experience and opinion more easily than we could. This society, however, is the American Society of Civil Engineers, it includes engineers in all branches; there is no reason why the engineers in the different branches should not associate themselves together in sections, or why we could not do more committee work along the various engineering lines than we have done in the past.

I believe, therefore, that we should favor the establishment of branches of the society in various parts of the country, and of student branches in the several technical schools; and that we should urge our committees to activity, supply them with funds, and perhaps pay the mileage of members who attend meetings. The society is rich, and it is not a philanthropic institution. If members give their time to committee work, I see no reason why they should be expected to give money, and the expense of attending many meetings may not seldom be considerable.

Moreover, we have been very loath to take any steps in formulating answers to questions which are largely matters of opinion; and we have done, thus far, little or nothing to influence public opinion in regard to questions of the day. I believe that we could and should go much further in these directions; that we should step forward, take the initiative and become a moving force in the community. Let me make some more definite suggestions.

In the first place, I believe we should have a standing Committee of Public Relation, its province being to keep track of all public affairs involving engineering questions directly or indirectly, in all the states in the Union, and to take such action as may be deemed desirable to insure a wise treatment of such questions. This committee might perhaps consist of president and secretary of the society ex-officio, of a certain number of members of the Board of Direction to be appointed each year by the president, and of a certain number of members of the society not members of the Board of Direction, to be nominated by the Board of Direction. These outside members might be in considerable number, perhaps one or more from each state or group of states, so that the committee could keep in touch with public affairs affecting the profession in all parts of the Union.

Further, our Committee on Engineering Education should, in my opinion, be enlarged, supplied with funds, and encouraged to active and exhaustive work. If we could lay down the principles which we believe should govern in engineering education, the general curriculum which should be adopted, the proportion of the humanities which should be included, and similar matters, we might, I believe, do much good and, while still leaving ample room for individual initiative and divergencies in practice in different institutions, render effective aid to those teachers who are striving to resist some prevailing tendencies.

In the next place, I believe it will he wise to have more committees of the society, dealing with specific problems, than we have had in the past. You have before you at this meeting, I am glad to state, a report from the Board of Direction stating that, as provided in the Constitution, it has voted to appoint two special committees to deal respectively with the regulation of streams and with uniform water legislation. I believe that still other committees could be appointed to advantage. We have no reason to be afraid of having too many committees. We should, rather, be sure that we lose no opportunity to exercise legitimate influence on public opinion or to aid in the solution of large problems. We might well, I believe, have a standing committee on conservation, another perhaps on corporation legislation, another on the history of American engineering. Let us give our earnest attention to this matter and let us not hesitate to suggest any and every means that may occur to us to promote the welfare of the society, of the profession, and of the public. The Board of Direction will be always ready, I am sure, to act promptly with such members of the society who can show a proper field for all legitimate action.

Reviewing then, the points which I have brought to your attention, I have endeavored to show that the problem of the times is pre-eminently a social problem. I have outlined some of the tendencies of the day, as they appear to me. I have given the reasons for my belief that it is the duty of engineers to aid in the solution of these problems and that by training and experience they are well qualified to do so. If my tone has appeared to indicate a pessimistic attitude toward the tendencies of the day, I fear I must plead guilty in some degree to the imputation; whether wisely or not, as the years have gone by, I have grown more conservative and I find myself having little sympathy with many of the tendencies which I seem to see about me. I believe that this age will be looked upon by future generations, not as an age of progress, but more distinctively as an age of deterioration, an age of fads, frivolities, fancies and follies; of much reading and little thought; an age of impulse rather than an age of reason. I am not alone, however, in a feeling of dissatisfaction. M. P. Leroy Beaulieu, writing in 1890, expressed himself as follows:—

"Every age is characterized by its particular craze. The present craze is for education, unlimited and injudicious, and for philanthropy equally unlimited and injudicious, both absolutely superficial. By their aid we have succeeded in producing a mental condition and in creating certain social circumstances which are most unfavorable to the growth of the population."

But, after all, it is only an epoch in the history of man. It will pass away, and others will solve the problems that we leave to them. May we do our part, as members of one of the greatest professions, to help direct the tendencies of the day in such manner that our successors may look back upon us with approval and not with blame, and that we may aid in forwarding the true progress of mankind.

WIRELESS IN AUSTRALIA.

The acting Australian Postmaster-General states that the wireless station at Darwin (Northern Territory) now being built will cost about £90,000. The station will have a radius of 2,000 miles, touching Singapore on one hand, and Sydney on the other. It will form the apex of a wireless triangle, of which Sydney and Perth will be the other points. The surplus electric energy at Port Darwin, it is expected, will be supplied to consumers at a low rate. The Darwin stations will be capable of communicating with any system which may be established by the British Government. Already wireless stations have been provided at Perth, Adelaide, Melbourne, Hobart, Sydney, Brisbane and Port Moresby (Papua). At Townsville and Cooktown masts for new stations are already up, and at Rockhampton arrangements are well advanced for completing the equipment. At Geraldton, Esperance, Roeburn, Broome and Wyndham construction work is being pushed ahead, and it is expected that the chain will be completed before the end of the year.

PRESSURE FILTRATION PLANT AT HAILEYBURY, ONTARIO.

The town of Haileybury, Ontario, has been the first to follow the British practice in regard to the use of British pressure filters for the purification of its domestic water supply.

The installation of a chlorination plant did not satisfy all the requirements for a potable and safe water supply, on account chiefly of the large amount of vegetable matter present in their raw water.

In April the filtration plant which last year's council and the present mayor, Mr. N. J. MacAulay, decided to have installed was turned on, and has since been operating with considerable success.

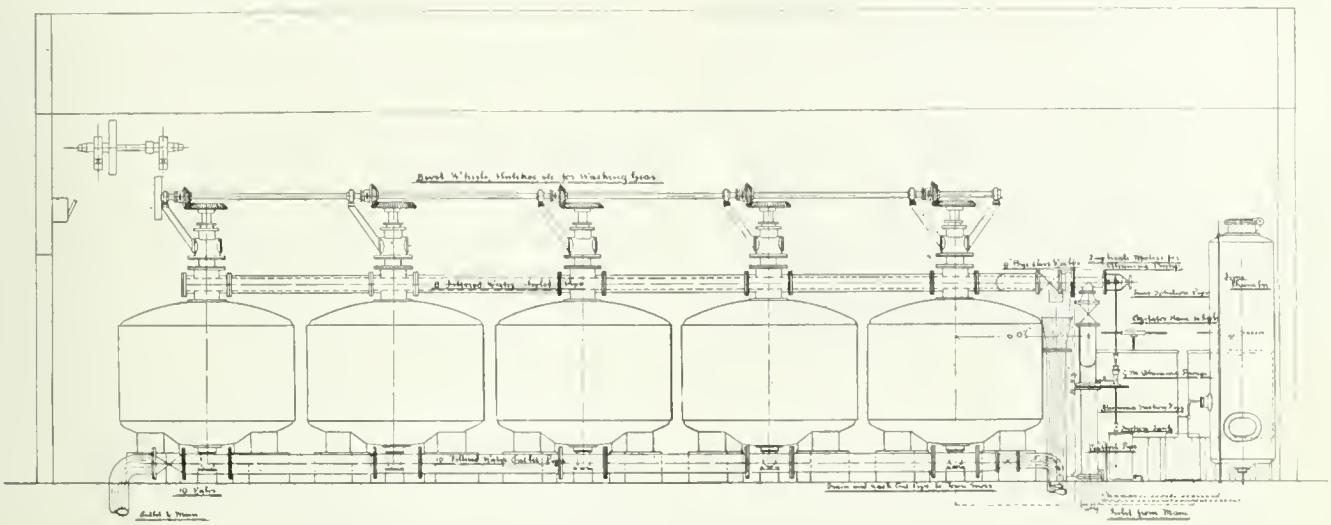
The source of the water supply is Lake Temiskaming, at the head of the Ottawa River. It is very highly colored, and is frequently very turbid with fine clay, while containing bacteria varying from 100 to 10,000 per cubic centimeter.

The alkalinity is also very variable owing to the rise and fall in the water level at different seasons, and most of the sewage of New Liskeard and Haileybury is discharged into the lake.

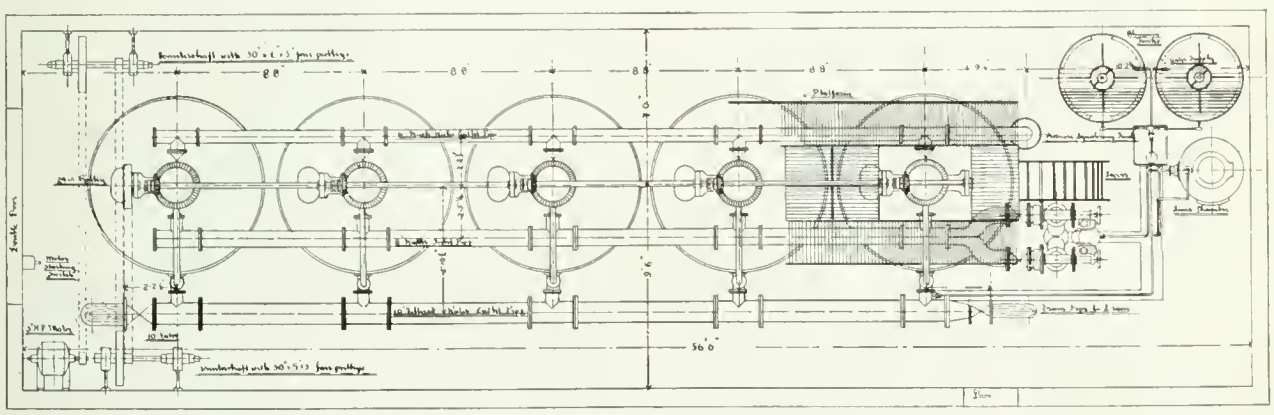
These conditions made the success of any filter plant very doubtful, but since the operation of that installed there has been a clear and sparkling water turned into the mains, without the slightest trace of color, or any turbidity, and according to the last bacterial analysis a reduction from 1,040 bacteria per cubic centimeter to 10 per cent. per cubic centimeter without the use of chlorine or any other disinfectant or sterilizer, or 99 per cent.

The cuts show a view of the plant and the platform for operating the cleaning mechanism, plans of the complete plant, there being no sedimentation basins or clear water reservoir, and a sectional view of one of the filters.

The inlet to the filter house is connected with the supply main, which was cut and had a branch inserted. The outlet end is connected in the same manner, except that a by-pass valve was placed in front of the branch to allow of the filters being cut out if necessary, or to diverge the raw water into the inlet to the filters.



ELEVATION.



PLAN.

Fig. 1.—General Arrangement of Haileybury Plant.

The plant has a capacity of one million Imperial gallons per day as a maximum, and operates under a working pressure of 100 lbs. per square inch. It is housed in a brick building 60 feet long by 18 feet wide, situated just above the pump house, which is placed alongside the lake. The water is delivered through the pump into the filters, through to the main, and thence on to the distribution system, and the town reservoir. The reservoir is placed on the hill above the town, so that a pressure of 85 lbs. per square inch is

available at the lowest points when the pumps are not in use, and is filled while pumping by the excess over the town's requirements in the five hours' pumping.

Inside the filter house is located a lime chamber, and duplicate alumina tanks constructed of steel, five Bell patent vertical type pressure filters, and the necessary piping, valves, washing motor and alum pumps.

As the raw water enters it passes through a venturi pipe into the throat of which is connected the down pipe from the lime chamber, while before entering the construction a pipe is led into the foot of the lime chamber. Lime is filled from

Fig. 2.—Interior View of Filter Plant at Haileybury.

a wrought iron platform on the top of the lime chamber in pails after being well slaked and the top closed. The addition of lime is then controlled by a valve on the town pipe, which is opened or closed until the manometer registers the desired quantity, so that the control is practically automatic.

In one of the alum tanks a solution for the day is made up, dissolved and put into use, while the duplicate tank is prepared for the following day's solution. Each tank is connected into the delivery pipe with a valve on each branch, so that by opening or closing either tank can be used at will. There are also drain pipes connected to the foot of tanks for cleaning and running off the liquor when it is required to do so. These are connected to a tile field drain running into the town sewer system.

A steel platform facilitates the operation of the alum tanks in which are placed agitators requiring to be revolved occasionally when the alum is dissolving. Under this is placed the equalizing tank, which is filled from alum tanks, controlled by a ball valve. From the equalizing tank the alum solution flows to the alum suction tank ready for delivery into the raw water, all the alum pipes being constructed of copper pipe with gunmetal fittings.

The raw water rises to the supply pipe to the filters, and revolves a turbine in proportion to its velocity situated inside the supply pipe. This turbine, by means of a worm gear, operates the gunmetal alum pumps also in proportion to the volume of water passing through the pipe, which pump up alum solution from the suction tank and deliver it into the raw water before it reaches the turbines. In this way the turbines can mix it intimately with the water and ensure absolute homogeneity in the distribution of the alum.

The supply pipe is brought by means of branches into the filter supply pipe. On each branch a valve is placed, and a turbine is connected. Only one of the branches is put into use at a time, and one of the alum pumps, the other being used as a duplicate in case repairing or overhauling is required.

Now that the raw water has received a definite proportion of lime and alum, it is in a 10-inch pipe delivering through branches into each of the filters, through which it passes into the collecting pipes out into the 10-inch outlet pipe in the town main.

In this plant and all others constructed by the same company the action of the chemicals added is to prepare the sand bed for effective operation in extracting the chemicals and impurities rather than to drug the impurities and then remove them, so that the minimum of chemical is required. Hence, the reason for the careful control of lime and alum, the latter being controlled by the strength of the solution and an ingenious arrangement on the alum pumps, whereby the length of the stroke can be shortened or lengthened at will, simply by turning a hand wheel while in operation.

The lime reacts on the alum and precipitates a sticky gelatinous matter which entangles the impurities in the water, and deposits them on the sand bed in the filters, in a similar manner to the work performed by the white of an egg in bringing down the grounds of coffee.

The section of one of the filters will explain fully the workings of these, while a wrought iron marine type platform is erected along the top of them to facilitate the other operations necessary, as will be further described.

Inside the filter house are placed two pressure gauges and two test taps, which are connected to the inlet and outlet side of the filters.

The test taps are tested periodically for alkalinity to show whether there is any alum in the water passing through the filters, or whether there is sufficient alkalinity to decompose the alum which is being added.

So far, since the plant commenced its operation, there has been no trace of alum in the filtered water, and it is guaranteed that none will ever be present.

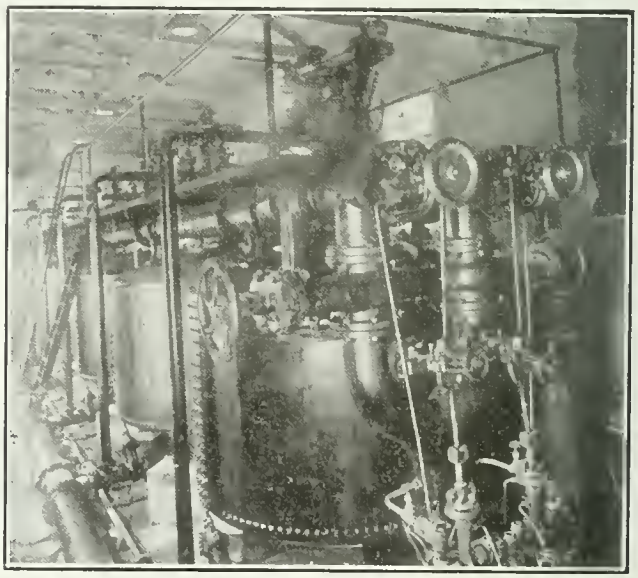


Fig. 3.—Installation at Haileybury, Ont.

When the pressure gauges indicate a loss of five pounds pressure between the inlet and the outlet side of the filters, the operator washes them out, as they are clogged up with the sediment which has been extracted from the raw water.

The wash-out is accomplished with less than one per cent. of wash water, occupies about twenty minutes of time, and is done by closing the inlet valve on the filter to be washed and opening the wash-out valve. The washing motor of 2½ horse power is switched on to revolve the washing gear shaft, and the clutch on the filter thrown in to allow of

agitation. Then the agitator valve is opened which directs high pressure jets of water through the hollow agitator arms into the sand in a lateral direction, forcing all sediment out so that the reverse flow raises it up and out to wash out the drain.

The wash-out water, when settled in a cylinder, is composed by bulk of one-third sludge and the remainder water. Each filter is washed in turn without any interruption taking place in the filtering action.

If it is desired to drain out any one filter all valves on that filter are closed, and the filter is then drained by means of a small drain pipe into the field drain.

The plant was erected and put in operation by the Bell Filtration Company of Canada, Limited, 305 Kent Building, Toronto, to the design and supervision of Mr. H. W. Cowan, C.E., their consulting engineer, and is very highly spoken of by all the residents of Haileybury, and those who have inspected it.

It is the first municipal plant of Bell patent filters to be installed in Canada, although every other country in the world, excepting the United States, have many installations. Several other plants are under way, and judging by the operation of the Haileybury plant, promise to solve the difficulty of treating water under conditions hitherto deemed untreatable.

AUSTRALIA'S RADIUM INDUSTRY.

In view of the cost and increasing use of radium, information as to radium mining in South Australia, contained in a review of mining operations in the state during the latter half of 1912, compiled by the chief registrar of the department of mines, is of more than ordinary interest.

At the Radium Hill mine, near Olary, 257 miles north of Adelaide, a considerable quantity of ore has been raised. This is concentrated at the magnetic separator plant in the mine, and shipments of the concentrate forwarded regularly to the company's works at Woolwich, on the Paramatta River, near Sydney. These works, which can now treat about ten tons per week, have, it is stated, cost over £15,000.

The directors report that "pure radium bromide has been produced. Although only 2½ milligrams were fully prepared, it proves that radium bromide of a purity of between 1,800,000 and 2,000,000 radio-activity can be procured from the company's ore, and there are, approximately, 350 milligrams of radium in the laboratory in various stages of purity, which will receive its final preparation and be available for sale automatically week by week henceforth. One hundred and twenty tons of concentrates have been smeltered, of which 95 tons have been treated for about 350 milligrams of radium, which is equivalent to an extraction of 32.3 milligrams per ton of concentrates." The company also proposes to utilize the various by-products contained in the ore.

The South Australian Radium Proprietary holds leases adjoining and to the northeast of the Radium Hill Company's property. Four shafts have been sunk, and a considerable amount of development work has been done. The Rare Metals proprietary, working on claims about three miles northeast of the Radium Hill mine, has done a considerable amount of prospecting work, and raised about seven tons of lode material, analyses from which are satisfactory.

At the property of the Radium Extraction Company of South Australia, Mt. Painter, no work was done during the period under review. The directors' report states that some good ore was picked out and despatched before work ceased, and one shipment of about 2¼ tons realized very satisfactory prices.

THE SCIENTIFIC SELECTION OF PAVEMENTS.

By W. W. Crosby, D.Sc., M. Am. Soc. C.E.*

The following article has received a good deal of press comment recently, especially from engineers in Great Britain. The writer is of the opinion that the science underlying the development of good roads is in need of careful study for the purpose of mathematically comparing the many kinds of road materials and construction methods with which highway engineers have become fairly familiar during the past few seasons. He claims that the problem of proper selection is most pressing, considering the fact that knowledge of road materials, new and old, is rapidly advancing, and that the demand for efficiency is making strides of even greater proportion. It would seem possible that a large amount of the personal element could be eliminated and that the practice of basing the selection on opinion alone could be replaced by scientific methods.

The suggestions which have been presented in various forms on previous occasions in the engineering press are called to the attention of highway engineers by Major Crosby in "The Municipal Journal." He further suggests the immediate commencement of steps for the standardization of the scientific method of selection. The importance to the roadway movement in Canada of the suggestions contained, and the value of impressing upon road builders the superiority of proper selection over methods of more or less personal nature, are factors which indicate that "The Scientific Selection of Pavements" is a paper which will be of great interest.

For convenience, in this paper any artificial road crust will be referred to as a "pavement," and "road" will be considered synonymous with "street" or "alley."

On a road requiring a pavement for reasons of economy and satisfaction, conditions are seldom duplicated. A pavement ideal in one instance may or may not be so in another. It has been suggested that, in general, the requirements for being ideal will be the same in all cases, but the various classifications may have decidedly different importance in different cases. That is, in one case low first cost and low maintenance cost may be most important. In another case, ease of hauling and lack of slipperiness may govern; while in another, sanitariness and noiselessness may overbalance all other considerations.

The main classifications suggested for consideration in the selection of an ideal pavement for any case are given as follows:—

First cost (on a basis of dollars and cents).

Maintenance cost (on a basis of dollars and cents plus interest on first cost).

Durability (ease and infrequency of repairs).

Resistence to traction (self-explanatory).

Non-slipperiness (self-explanatory).

Sanitariness, cleanliness and noiselessness (self-explanatory).

Acceptability or agreeableness (æsthetic or personal).

In assigning values to these qualities, it will be found in the interests of accuracy and convenience to subdivide them somewhat further, and in order to assist in getting farther away from the personal factor, the writer suggests for consideration the following table, with the values opposite the classifications as assigned by various authorities:—

*Chief Engineer, Maryland Geological and Economic Survey, Baltimore, Maryland.

Table I.—Showing Relative Values of the Various Qualities of an Ideal Pavement.

Qualities.	Baker.	Tillson.	U.S. Bulletin.
First cost—cheapness	15	14	14
Maintenance cost—cheapness	—	—	—
Durability	—	21	20
Ease of maintenance	20	10	10
Ease of cleaning	10	15	14
Low tractive resistance	10	15	14
Non-slipperiness	5	7	7
Sanitariness	25	13	13
Noiselessness	—	—	—
Acceptability	15	—	4
Favorableness to travel	—	5	4
Total	100	100	100

While the authorities quoted have not done so, the writer would suggest the sub-division of the items on the following bases:—

"Maintenance cost" into "maintenance cost" (i.e., on a basis of dollars and cents), and "durability" (i.e., on the basis of ease and frequency of repairs required). "Acceptability" into "noiselessness" (which explains itself), "acceptability" (i.e., on a basis of personal or local preferences of abuttors and æsthetic considerations), and "favorableness to travel" (i.e., on the basis of absence of bad effects on animals and vehicles using the pavement).

He would then base his values for "ease of maintenance" in the list on the ease of actually making the repairs necessary (i.e., whether or not special outfits, such as asphalt plants, were required or not), and "ease of cleaning" on the requirement for unusual machines, the frequency of cleaning required, and the actual cost in dollars and cents.

It will be noted that, while the values assigned by Tillson and the U.S. Bulletin are practically identical, a considerable variation exists between them and those given by Baker, and it has been suggested that this variation results from consideration of different conditions. Apparently Tillson and the U.S. authorities had in mind pavements subjected to heavy hauling, while Baker was considering a type of pavement for residential streets. This illustrates the former reference to differences in ideals or to the relative importance of the classifications composing the ideal.

Hence, it seems to the writer that the standardization of a table for the selection of pavementts covering all conditions, character of traffic and with positive values assigned to each kind of pavement is impracticable. Rather, on the other hand, should the effort be made for the standardization of a set of tables—one for use with each class (not amount) of traffic under each class of circumstantial conditions. That is, the writer would suggest a set of tables as follows:—

Table A.—For use on streets in a commercial district where heavy hauling is prevalent or likely to be so; such, for instance, as along the docks or freight depots.

Table B.—For use on streets in a commercial district where heavy hauling is not preponderant nor likely to be so; such, for instance, as about the retail stores of a city.

Table C.—For use on streets carrying occasional heavy loads, occasional pleasure vehicles, and a large proportion of vehicles of moderate weight; such, for instance, as the main thoroughfares of the "down town" portions of a city.

Table D.—For use on streets of the residential portions of a city and where street railway tracks do not exist. (Where street railway tracks exist, use for the width occupied by the rails plus 4 ft., Table C.)

Table E.—For use on city streets where special conditions exist; such as around hospitals, court-rooms, etc.

Table F.—For use on boulevards and on places where æsthetic conditions are preponderant.

Table V.—For use on main country roads, such as "State roads" carrying fairly heavy mixed travel.

Table W.—For use on secondary country roads carrying moderate travel.

Table X.—For use on minor country roads carrying farm travel almost wholly.

Note that the classification is based on the kind of travel known to require support by the pavement, or likely, from the situation of the road, to so require, and not the amount of travel. Consideration of the latter factor will enter when, for any particular case, comes the entering of figures of value for each kind of pavement.

Assuming that the main classifications of travel are given in the above list (though, of course, it is possible to extend the latter), a set of values for the components of the ideal in each case can be made, as shown in Table II.

Table II.—Showing Values for Components of Ideal for Different Tables.

Components	Tables A	B	C	D	E	F	V	W	X
First cost—cheapness	10	10	10	12	10	8	15	15	15
Maintenance—cheapness	20	20	20	15	10	10	25	25	20
Durability	5	5	5	5	5	7	7	7	7
Ease of maintenance	5	5	5	5	5	5	8	10	10
Cleanliness	5	5	7	10	10	12	5	5	5
Low tractive resistance	20	15	10	5	5	5	10	5	5
Non-slipperiness	15	15	12	10	10	10	10	10	10
Sanitariness	5	8	10	13	15	10	5	5	5
Noiselessness	5	7	8	10	20	8	5	5	5
Acceptability	5	5	8	10	5	20	5	5	8
Favorableness to travel	5	5	5	5	5	5	5	8	10
	100	106	100	100	100	100	100	100	100

The application of the tables to the selection of a pavement would be as follows:—

If the case of a street along the freight station is taken, Table A may be applied thus:—

Example I.

Qualities	Ideal (Table A)	Values for Vit. brick	Grouted stone block	Pitched stone block	Grouted Durax	Sheet asphalt
First cost	10	10	8	8	7	10
Maintenance cost	20	8	18	15	20	6
Durability	5	2	5	4	5	3
Ease of maintenance	5	5	5	4	5	2
Cleanliness	5	5	4	3	4	5
Low tractive resistance	20	20	15	10	18	19
Non-slipperiness	15	3	8	13	15	2
Sanitariness	5	5	4	3	4	5
Noiselessness	5	4	1	2	3	5
Acceptability	5	4	4	4	5	4
Favorableness to travel	5	2	2	3	5	4
Totals	100	68	74	69	91	65

Or, in the case of a residential street without street railway tracks:—

Example II.

Qualities	Ideal (Table D)	Values for Vit. brick	Durax	Sheet asphalt	Water-bound macadam
First cost	12	6	3	7	12
Maintenance cost	15	12	15	10	8
Durability	5	4	5	3	2
Ease of maintenance	5	4	4	2	5
Cleanliness	10	10	8	10	4
Low tractive resistance	5	5	4	5	4
Non-slipperiness	10	3	8	2	10
Sanitariness	13	12	8	13	6
Noiselessness	10	6	4	10	8
Acceptability	10	8	6	10	8
Favorableness to travel	5	3	2	4	5
	100	73	67	76	72

And in the case of a secondary country road, we have:—

Example III.

Qualities	Ideal (Table W)	Values for Vit. brick	Plain concrete	Pitch macadam	Water-bound macadam
First cost	15	8	10	10	15
Maintenance cost	25	25	20	20	10
Durability	7	7	5	5	3
Ease of maintenance	10	7	8	8	10
Cleanliness	5	3	3	5	2
Low tractive resistance	5	5	4	4	4
Non-slipperiness	10	4	7	5	10
Sanitariness	5	4	4	5	3
Noiselessness	5	3	3	5	4
Acceptability	5	2	3	4	5
Favorableness to travel	8	3	5	6	8
	100	71	72	77	74

The foregoing will perhaps serve to illustrate the idea the writer has in mind that mathematics can aid the highway engineer and help to reduce the personal equation in the important matter of selecting the proper pavement for any particular case. Of course, the tables suggested may be amplified or altered at the discretion of the individual. The principle remains the same.

For general cases and in order to furnish proper starting points to modifications for particular instances, it seems to the writer that the attention of the profession, the discussion of the question and the standardization of a set of tables as suggested above, and of their components and their values for an ideal pavement in each case, would be well worth while.

When this shall have been done, there will next be needed accurate information from records, uniformly kept, as to the cost of maintenance of the various kinds of pavements, and as to their behavior as to the other items or components of the tables under stated conditions of travel, so that values can be properly assigned, with as little "guessing" as practicable, to such components for the comparison of different pavements under any particular travel which is known to be expected in a specific case. Such records are now being collected and will probably soon be available.

NEW BRITISH CABLE SERVICE.

The new cable direct from Land's End (England) to Hongkong by way of Suez, Aden, Colombo, Penang, and Singapore, is to be laid during the present year. The Malta section to Alexandria is already finished, so that about 9,000 miles remain to be completed out of a total distance of 12,000 miles. The section from Colombo to Penang is expected to be ready by July, and the work on the other sections is to begin shortly. With the exception of a small land cable from Alexandria to Suez, the whole line will be under sea. It is said to be the largest ever laid, and is estimated to cost about $7,500,000. At present the time taken to transmit a 20-word message from Bombay to London in 2½ hours, while the distance from Colombo to Bombay occupies another hour or hour and a half. By the new cable it will take only ten minutes to transmit a message from Colombo to London, while the cost of cabling will be greatly reduced. By means of the "slot" system the message is mechanically transmitted from section to section, and is not touched by hand till it reaches its ultimate destination, thus reducing to a minimum any chances of mutilation in retransmission. The cable will be under European management, and will be worked entirely by European operators.

COAST TO COAST.

Toronto, Ont.—C. A. Magrath, former member for Medicine Hat, Alta., in the Dominion House, and a member of the Canadian section of the International Waterways Commission, has been named as the probable choice of the Ontario Government for the chairmanship of the Provincial Highways Commission, through which the Government will carry out the vast road development scheme promised last session. It is generally understood that W. A. McLean, present provincial highways engineer, will be a member of the commission, with supervision over the engineering and construction end of the scheme. Just now Mr. McLean is abroad, where he went partly to attend the International Roads Congress, but chiefly to journey about and study advanced road construction methods of Britain and Europe. Upon his return, and after the appointment of a commission, it is probable the commissioner will visit the United States and study methods there. The government's third choice is somewhat in doubt, but the name of Reeve Henry, of the York Highways Commission, has been spoken of. Reeve Henry is a road enthusiast, and would represent the farming interests of the province on the board.

Victoria, B.C.—A meeting of leading state highway commissioners and the manufacturers of horse-drawn wagons and motor-driven trucks is the suggestion of Chairman George C. Diehl, of the American Automobile Association national good roads board, who contends that the time has arrived when those interests can advantageously discuss the drafting of suitable legislation governing the width of tires and the weight of loads. After an interchange of views he holds a committee could prepare laws, the passage of which would be practically assured when put forward by the chief highway officers of the various states. "Many states have enacted laws which endeavor to regulate the width of tires of vehicles, but unfortunately there has not been strict enforcement of these regulations," says Mr. Diehl. "The width of tires is one of the important factors in highway construction and maintenance. Narrow tires, especially during the wet season, form ruts in improved roads, and in many instances, where the roads are weak, break through the surface, causing subsequent rapid destruction of the highway. One great difficulty in enforcing wide tire ordinances with horse-drawn vehicles has been that while less traction is required, with wide tires, on slippery clay or hilly roads it is very difficult in wet weather to manage a horse-drawn vehicle with wide tires, owing to its tendency to skid and slide into the ditches. Instances are frequent where in a journey a farmer must drive over miles of slippery road and only have a few miles of improved highway, in which case he would naturally prefer to use narrow tires for the entire distance, rather than to attempt the use of wide tires over the slippery section of the road. There is no question that protection and economical maintenance of improved highways require that narrow tires should be discarded, and ordinances must be enforced which will prevent their use on main travelled highways which have been improved at great expense. If a vehicle owner desires to use narrow-tired wagons on slippery roads, he must be absolutely prevented from using the same tires on improved roads. Equal, if not greater, damage can be done to the highway with tires of insufficient width on motor trucks.

Victoria, B.C.—Preparations for more active work on the Sooke Lake waterworks system are being made by Water Commissioner Rust, and a few more men have been added to the force on the ground, about fifty being now engaged. A camp is being established at the lake, and supplies and

materials required for the same are now being shipped out. The city has made a satisfactory arrangement with the receiver of the Westholme Lumber Company whereby the plant required by the city can be secured on a valuation to be decided by independent valuators. This plant consists of tents, light rails, tools of all sorts, and other necessary apparatus, which, unless its use was permitted by the receiver, the city would have to purchase. Water Commissioner Rust stated that as soon as work actively commences the force of men will be increased to about 150. Mr. Wynn Meredith, the city's consulting engineer on the work, has prepared the specifications for the tenders for which the city is now calling for the supply of cement pipe and steel plate for the pipe line. Cement pipe for about twenty-seven miles will be secured for the flow line from Sooke Lake to Humpback Reservoir, and the steel pipe will be required for the pressure line from that reservoir to the city. The estimated cost of this part of the work is between $700,000 and $800,000. With the recent sale of debentures the city has on hand ample funds wherewith to permit of active prosecution of the work, and as soon as the preliminaries are fully settled the undertaking will be proceeded with as fast as possible.

Toronto, Ont.—It is understood that the plan of the Ontario Government for establishing a good roads commission to supervise construction in the older parts of the province embraces several features. There is likely to be a joint chairmanship, one official to be in charge of the practical administration, and the other will deal with financial and the general outline of the scheme. In addition, there will be a complete reorganization of the co-operative system, in which the government advances to counties desiring it a grant of one-third the amount to be expended in the good roads movement. A change in the percentage has long been considered by the cabinet, and legislation will in all probability appear at the next session to change the rate from one-third to one-half. The fact that the maintenance of roads by the counties is not popular has been instrumental in resolving the government to assume the upkeep in future. The actual means have not yet, however, been decided on, but it has been suggested that the government grant be reserved in large part for that purpose. Premier Whitney recently stated that the personnel of the commission had not yet been decided upon. It is understood, however, that Provincial Engineer W. A. McLean will occupy a place, probably as administrative chairman. The interests of Eastern Ontario may be regarded in choosing a commissioner from that district.

Victoria, B.C.—A prominent automobile man, in discussing the relative merits of the telephone and motor car, made the following interesting statements: "The telephone and the motor car have done more for the farmer than any other invention, with the possible exception of the reaper. We have heard a great deal of late about the necessity of a return to the farm. That is, various social and economic conditions of modern life have prompted a movement to turn the tide which has been running cityward back to the farm. Farmers' sons for a while were irresistibly lured to the city, and the reason was that farm life was too sordid, uninteresting, too limited in its opportunities for rational enjoyment for the young man who had argued that the high cost of living, the congestion in cities, the bitterness of competition in all walks of life could be reduced and alleviated if farming as a profession was made more attractive. The telephone and the motor car have been doing a great work in solving this problem by doing just what the students of sociology and economics have asserted must be done. That is, they have revolutionized farm life by modernizing it, keeping it in close touch with the outside world and bringing the city almost to the isolated farm. Nowadays the farmer without a telephone is an exception. This great convenience keeps him in instant touch with his neighbors and with the city. It has had an untold effect in making the life of the farmer more bearable and attractive. No less important in achieving a revolution in living conditions is the motor car. Beyond all that it has proved of economic value because a machine is serviceable for many tasks that can be accomplished far more efficiently and expeditiously than with the horse and wagon. Any one who doubts that the farmer has taken kindly to the automobile should visit the country churches, the country fairs and the county seats, and see the machines parked. The number of automobiles in evidence will certainly prove illuminating."

Ottawa, Ont.—There will not likely be any opposition to the city co-operating with the Dominion Government in preparing plans for the enlargement and beautification of the Capital and its development along proper lines. The board of control in its report to the city council will recommend that the city concur in the suggestion which was made by the minister of finance for the appointment of a commission to prepare plans covering Ottawa, Hull and their environs and dealing with parks, transportation and other features that are serious problems in the development of the Capital. The proposition made by the government was that half the cost of the commission should be borne by the government and the other half by Ottawa and Hull. The board of control is recommending to the city council that Hull be asked to bear one-fifth of half the cost and that Ottawa bear the remaining four-fifths of half. The city council seems unanimously in favor of co-operation and it is not likely that any opposition will be raised. It is understood that as soon as the cities agree to the proposal the government is prepared to name its commissioners, the mayors of the two cities also being members.

Toronto, Ont.—An important conference between the city of Toronto and the townships of Etobicoke, York and Scarboro' was held recently. City planning beyond the limits of Greater Toronto was discussed, a plan for diagonal roads in Etobicoke, York and Scarboro' engaging the attention of the delegates. It was decided to adopt the principle that no road must be less than 66 feet wide, and that through roads must be 86 feet wide. The townships interested in the schemes will have to obtain legislation before they can establish building lines to prevent people from building up to the street line as at present. Ald. Sam. McBride presided, and promised that the city would do everything that could be done to help the townships secure the necessary legislation. Assessment Commissioner Forman explained the principles of the homologated line and its power to fix street building lines indefinitely. As a result of the conference each township will prepare a map showing which of the proposed diagonal streets will be 66 feet wide and which will be 86 feet wide. Then a general map will be prepared to conform with the smaller maps, the township maps being submitted first at another meeting of the city and township officials.

Ottawa, Ont.—Canada will have the longest and loneliest motor road in the world, according to the recent decision of the government to build a motor road into Dawson City. Fifty thousand dollars has been voted for the purposes of this road, and a couple of other such votes will be necessary to finish it. At the present time Dawson is only reached by stage in winter, when there is a deep coating of snow on the ground. It is the intention of the government to build a road for motors 400 miles in length, from White-horse at the

head of Yukon's two thousand miles of navigation, right into Dawson City. Dr. Alfred Thompson, M.P. for Yukon, who obtained this grant, will take surveyors with him into the territory to start the work on his return to his constituency. At the present time the motor has penetrated into the heart of Africa, and almost everywhere else. Tourists go thousands of miles in order to travel over some road, hitherto unknown to the power car. And thus, when this motor road is finished into Dawson, it will not only open that Canadian city to the tourist traffic of the world, but attract tourists from many lands.

Ottawa, Ont.—The improvement works and storage reservoirs on the Upper Ottawa by dams at Temiskaming and Quinze are dealt with in the annual progress report just published by the public works department. The storage of the surplus water of the Ottawa River has been demanded by various interests for a great number of years. In 1902 and 1903, the matter was particularly brought to the attention of the government, memorials being presented asking that this work be undertaken as a national enterprise. During periods of low water in the river, navigation is rendered difficult, and the power developments supplying energy for industries and public utilities suffer severely. To remedy these conditions, it was represented that the best scheme would be to establish some system of storage reservoirs at the head waters of the Ottawa River, by which some of the surplus waters of the spring could be collected and conserved, to be released gradually during the low period and thus augment the low flow. The total appropriation in 1912 for construction work was $353,000, and the total expenditure since storage commenced is $609,347. The principal feature of the report is that by C. R. Coutlee, engineer in charge, who tells in detail of the work accomplished by the department by day labor on the storage dams at Quinze and Temiskaming, and who makes some interesting general comment. He says in part: "The full benefits of the great storage system now nearing completion, will not be felt until subsidiary reservoirs are created all the way down stream. The Mississippi, for instance, is not benefited by its reservoirs much below St. Paul, say 150 miles down stream. Now, if private capital begins building dams in the river, there will be no general system observed and chaos will result. Owing to the great cost and the divided control of the river between Ontario and Quebec, companies would often pen up only one side of the stream. This would ruin the river for navigation and an attempt to use the other side for power would be met with law suits and great construction difficulties. Private dams take no heed of power possibilities above and below their immediate site and the money is not always available to make them strong beyond chance of accident. Inspection would be lacking both as to upkeep and as to the control of the water flow and riparian rights." The dams now are practically finished and their benefits are already apparent in low water seasons.

Ottawa, Ont.—That the government is fully alive to Canada's greatest problem, that of transportation and its allied facilities, is indicated in the more than generous appropriation for the purpose made this year. The engineering staff of the public works department is applying itself to the preliminary arrangements for calling of tenders on several new and very expensive works and of proceeding with other undertakings already in progress. After session there is always a demand by members of parliament to have works in their respective constituencies started immediately. This cannot always be done, as time is required for the preparation of plans. However, the intention is to have all the works comprised in the forty-five million dollars appropriations under way before the year terminates. All parts of the country have been looked after in what may be described the big national works. Halifax is to have new terminals and docks for the I.C.R. costing eight or ten millions, while a big dry dock is also to be built. St. John has the extensive Courtenay Bay improvements in full swing including also a dry dock. In a few days a contract will be awarded for the largest dry dock in America at St. Joseph de Levis, opposite Quebec, while the River St. Charles is being deepened and many new terminal facilities added for railway and steamship services. At Montreal the harbor board is proceeding on the strength of government advances with the yearly stage of improvements to aggregate in cost $18,000,000. Tenders will be called this week for the Toronto harbor works to cost $6,000,000, while a good start has been made and bigger plans are in view for similar works at Hamilton. On July 17, the tenders for the first section of the Welland Canal will be in and those for other sections will be called in a month or so. On Georgian Bay extensive dredging works are in progress and work being rushed on the Trent Canal, while at the Soo, with its abnormal shipping, a subsidized dry dock is under construction. Port Arthur and Fort William improvements consist of new docks and warehouses, grain elevators and harbor improvements. A system of internal elevators will be built on the prairies, those at Saskatoon and Moosejaw being already decided on. Out at the coast Vancouver is to have big docks and harbor facilities and a dry dock, while the similar works and breakwater at Victoria are well started. Esquimalt, in the extreme west, gets a first-class dry dock. Departmental expenditures in two years have doubled with the growth of the country and its coincident demands for up-to-date facilities for handling traffic have both necessitated and justified the extensive outlays now being started.

PERSONAL.

MR. F. W. PETERS, general superintendent of the British Columbia division of the Canadian Pacific Railway, who has been in Europe since April, has just returned.

MR. J. D. CRAIG, of the Department of the Interior at Ottawa, is in charge of the boundary survey from Mount St. Elias to the Arctic Ocean, and arrived in Skagway recently, expecting to complete the work before the end of the summer. The survey has been in progrss during the past four years.

MR. J. DARLINGTON WHITMORE, A. M. Can. Soc. C.E., has been appointed boro' engineer at Whangareé, New Zealand, and is taking up his duties at once. Mr. Whitmore was city engineer at Moose Jaw, Sask., for five years, until, in 1910, he opened offices as consulting, municipal and sanitary engineer.

MR. ALBERT NUTTALL, formerly erection superintendent, Structural Steel Company, and for the last two years superintendent of construction for Canada of the Cleveland Bridge Company, has been appointed superintendent of erection, bridge department, Canada Foundry Company, Limited, with headquarters at Toronto.

MR. P. W. WARD, who for the past two years has occupied the position of eastern manager for E. R. Watts & Son, Canada, Limited, and who resigned a short time ago, has accepted an appointment to the position of eastern sales manager for the Eugene Dietzgen Company, Limited. Mr. Ward will manage the eastern business of the firm in engineering and architectural instruments and supplies from the company's headquarters at 432 St. Catherines Street West, Montreal.

MR. COLLINGWOOD B. BROWN has been appointed to the position of chief engineer of the government railways

in Canada. Mr. Brown is a graduate of Cornell University and has been with the Canadian Pacific Railway for the last fourteen years, for the past two years of which he has been principal assistant engineer. Previous to that time he was division engineer at St. John, N.B., and at Montreal, and assistant division engineer at Calgary. He is a Canadian by birth with Kingston as his native city.

PACIFIC COAST CONVENTION OF THE A.I.E.E.

The Pacific Coast Branch of the American Institute of Electrical Engineers will be in convention in Vancouver, September 9, 10 and 11. The convention is in charge of a committee of prominent members, of which Mr. R. F. Hayward, of Vancouver, B.C., is chairman. A number of papers have been arranged for by the committee. The proposal is to present one paper at each session, giving ample opportunity for comprehensive discussions. Several interesting trips are also being arranged.

COMING MEETINGS.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

CANADIAN PUBLIC HEALTH ASSOCIATION.—Annual Meeting in Regina September 16, 17 and 18. General Secretary, Major Drum, Ottawa; Local Secretary, Dr. Murray, Regina.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held at Chicago, Ill., Feb. 16-20, 1914. Secretary, E. E. Kraus, Harrison Bld., Philadelphia, Pa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B. Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1230. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Bedford McNeill; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. J. B. Porter, H. E. T. Haultain and W. N. Miller and Messrs. H. W. Claudet, S. S. Fowler, R. W. Leonard and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

▲—Denotes an item regarding work advertised in *The Canadian Engineer*. +—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

PLANS AND SPECIFICATIONS ON FILE.

The following plans and specifications are on file for reference only, unless otherwise noted, at the office of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg, Man.:

BIDS CLOSE — NOTED IN ISSUE OF

16-7—Construction of sewer and water-works, Prince Albert, Sask. 26-6

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of *The Canadian Engineer* referred to.

PLACE OF WORK	TENDERS CLOSE	ISSUE OF	PAGE
Battery Point, N.S., extension of breakwater	July 14.	June 19.	76
Duncan Station, B.C., public building	July 7.	June 26.	76
Huntsport, N.S., construction of a wharf	July 17.	June 26.	78
Ottawa, Ont., supplying coal	July 14.	June 19.	84
Ottawa, Ont., Welland Canal	July 17.	June 12.	84
Ottawa, Ont., dredging rivers	July 8.	June 26.	78
Prince Albert, Sask., construction of sewer and waterworks	July 16.	June 26.	84
Prince Rupert, B.C., residence	July 7.	June 26.	78
Regina, Sask., construction of pavement	July 9.	June 26.	84
Saskatoon, Sask., bridge	July 15.	June 26.	84
Sea Gull, Ont., extension of wharf	July 14.	June 19.	78
St. Rose, Que., construction of works	July 7.	June 19.	76
St. Thomas, Ont., post-office	July 9.	June 26.	78
Toronto, Ont., concrete viaduct.	(No date)	.....	86
Toronto, Ont., cutting pulp-wood	Aug. 15.	.....	78
Toronto, Ont., supplying fire apparatus	July 8.	June 26.	78
Toronto, Ont., decoration work.	July 8.	June 26.	78
Victoria, B.C., laying reinforced concrete pipe	July 15.	June 26.	86
Walton, N.S., extension of wharf.	July 17.	June 26.	80
White's Bluff, N.B., construction of wharf	July 9.	June 19.	78

RAILWAYS—STEAM AND ELECTRIC.

Halifax, N.S.—Important plans for the improvement of the Intercolonial Railway are under consideration following the visit of Hon. Frank Cochrane to the Maritime Provinces. These plans involve the double tracking of the line from Moncton to Halifax. Mr. Cochrane and F. P. Gutelius, the new general manager of the I.C.R., have been making a thorough study of the conditions of the road as the time at their disposal would permit, and it is understood that the decision to have a double line of railway from Moncton to the new terminals at Halifax has been reached.

Montreal, Que.—The activities of the Canadian Pacific Railway and its influence on the financial, mercantile, manufacturing, and laboring interests of Canada are great. In the current year, the company's appropriations for the construction of additional railway mileage for cars and locomotives, terminal facilities at St. John, Montreal, Toronto, Fort William, Winnipeg, Calgary, Vancouver, and elsewhere, for ocean steamships, and hotel extensions on the telegraph system, shops, sidings, and improvements, generally in Canada, will approximate no less a sum than $100,000,000.

▲—**North Toronto, Ont.**—Tenders will be received up till the 12th of July for the construction of the substructure of a subway. Plans and specifications may be obtained from B. Ripley, engineer of grade separation, Toronto.

▲—**Ottawa, Ont.**—Tenders will be received up till the 29th of July, 1913, for supplying a steel pontoon gate lifter for Trent Canal. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, secretary.

Ottawa, Ont.—The Morrisburg and Ottawa Electric Railway Company desires to receive tenders for construction of ten miles of its line of railway, commencing from the city of Ottawa and extending in the direction of Morrisburg; such tenders to be based on the company's plans and specifications. Tenders will be received up to and including the 8th day of July, 1913, and the plans and specifications for proposed work can be inspected at any time up to the said date at the office of the Morrisburg and Ottawa Electric Railway Company, Canada Life Building, Sparks Street, Ottawa.

Regina, Sask.—The street car lines in this city will be extended at a cost of about $28,000, made up as follows: $12,000 for steel rails; $1,692 for ties; $11,000 for cement; $2,192 for street poles; $844 for trolly wires and overhead materials.

LIGHT, HEAT AND POWER.

+—**Montreal, Que.**—The Canadian Pacific Railway has awarded the CANADIAN GENERAL ELECTRIC COMPANY the contract for the electrification of the company's line between Castlegar and Rossland. It is intended to use 2,400 volts, direct current trolly system.

Vancouver, B.C.—Anticipation of the future power requirements of greater Vancouver and the probability of the electrification of the coast section of the Pacific Great Eastern Railway, the Bridge River Company, recently incorporated, plans to develop at least 200,000 horse-power in the Lilloette district. The expenditure involved will be about $8,000,000. The project calls for the building of a large dam on Bridge River and a tunnel one and three-fourth miles long through the mountain.

Victoria, B.C.—Tenders will be received up till the 7th of July for supplying poles, cables, etc. Plans and specifications may be obtained from W. Galt, city purchasing agent.

Winnipeg, Man.—Tenders will be received up till the 9th of July, 1913, for the manufacture and delivery of one-100 K.W. motor generator. Plans and specifications may be obtained from the Board of Control. M. Peterson, secretary.

GARBAGE, SEWAGE AND WATER.

Bolton, Ont.—Tenders will be received up till the 15th of July, 1913, for sinking a test well. Plans and specifications may be obtained from John McDonald, clerk.

+—Edmonton, Alta.—The Board of Commissioners have awarded the NEW YORK CONTINENTAL JEWELL COMPANY the contract for the addition to the filtration plant. The contract price is $117,000, and the contract must be finished by April 15th, 1914

+—Edmonton, Alta.—The Board of Commissioners have awarded W. H. ALLAN, SON & CO., the contract for supplying sewer pumps.

Fort William, Ont.—The ratepayers of this city have passed by-laws to provide for additions to the waterworks system and sewer system.

Hamilton, Ont.—Work on the west-end sewage disposal works will be commenced at once. The tender of the City Engineer for $62,000 was the lowest received and consequently he will do the work.

North Toronto, Ont.—According to a report of Commissioner Harris, $4,000,000 will be the cost of the construction of a trunk sewer and the outlets for a sewer service. At least three years will be required to complete the work, and Commissioner Harris strongly advises the use of septic tanks in the meantime.

▲—Prince Albert, Sask.—Tenders will be received up till the 16th of July, 1913, for the construction of sewer and water mains. Plans and specifications may be obtained from the office of *The Canadian Engineer*, Winnipeg; M. H. Baker, city engineer, and the City Commissioners.

▲—Toronto, Ont.—Tenders will be received up till the 8th of July, 1913, for the construction of a large number of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Mayor.

▲—Victoria, B.C.—Tenders will be received up till the 15th of July, 1913, for the laying of about 27½ miles of reinforced concrete pipe and appurtenances on the line of the Sooke Water Supply gravity conduit. Plans and specifications may be obtained from the Sooke Water Supply office, and C. H. Rust, Water Commissioner.

BUILDINGS AND INDUSTRIAL WORKS.

Bassano, Alta.—The ratepayers have passed the following by-laws:—$25,000 for expenditure on gas well and $5,000 on municipal hospital. G. R. Bond, secretary-treasurer.

Edmundston, N.B.—Tenders will be received up till the 14th of July, 1913, for school building on Indian Reserve. Plans and specifications may be obtained from the Department of Indian Affairs, Ottawa. J. D. McLean, secretary.

+—Fort William, Ont.—Messrs. Davidson and Smith have awarded the BARNETT-McQUEEN COMPANY the contract for the erection for the first unit of the elevator. It will be reinforced concrete construction and will have a concrete dock built facing the slip to the Government elevator. The contract price is $358,000.

Halifax, N.S.—Tenders will be received up till the 10th of July, 1913, for large supply of paint. Plans and specifications may be obtained from H. Donkin, Road Commissioner, Commissioner of Public Works and Mines, Halifax, N.S.

Hamilton, Ont.—The Victor Saw Works, Limited, the Canadian company of the Massachusetts Saw Works, of Springfield, Mass., will erect a plant in this city.

Hanover, Ont.—Tenders will be received up till the 21st of July, 1913, for the erection of a public building. Plans and specifications may be obtained from Thos. Hastings, Toronto, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Montreal, Que.—The Board of Control has awarded THEODORE LESSARD the contract for the construction of the Meurling Refuge. The contract price is $116,000.

+—Montreal, Que.—The Board of Control have awarded the COOK CONSTRUCTION COMPANY, of Sudbury, the contract for the final widening of the city aqueduct. The tender of the Cook Construction Company was for $2,322,552 with boulevards alongside the aqueduct banks from Pointe St. Charles to Lachine, and the tender of Quinlan and Robertson for the same work was $2,621,180.

+—Orillia, Ont.—The Dominion Government has awarded the SIMCOE CONSTRUCTION COMPANY the contract for the erection of a public building. The contract price is $40,000.

+—Ottawa, Ont.—The Dominion Government has awarded the PETER LYALL CONSTRUCTION COMPANY, Montreal, the contract for the new entrance and other improvements at Rideau Hall. The contract price is $125,000.

+—Ottawa, Ont.—The Dominion Government has awarded the SIMCOE CONSTRUCTION COMPANY, Simcoe, the contract for the erection of the new Customs House. The contract price is $995,000.

Port Arthur, Ont.—The Mackenzie and Mann interests are contemplating plans for a huge steel plant. The estimated cost of the plant is between five and eight million dollars and the work will occupy a mile of waterfront.

Quebec, Que.—As a result of the meeting of federal ministers in Quebec, it has been decided to immediately issue orders for the beginning of the public works promised for the city of Quebec, which include the building of a tunnel with entrance at Wolfe's Cove to St. Malo to connect with the Union passenger station; the Transcontinental Railway workshops at St. Malo, a grain elevator in the vicinity of Priest's wharf, Champlain Street; docks for shipping accommodation, and a passenger and freight depot for local traffic.

+—Regina, Sask.—The exhibition committee has awarded Mr. J. T. TRAUT, Regina, the contract for the erection of the new grandstand, the contract of $19,300 being the lowest, the five others ranging as high as $27,000.

Saskatoon, Sask.—Dr. G. E. Holmes has awarded MR. JOHN DAVIS the contract for the excavation of a new skyscraper. The building when finished will cost $250,000.

Simcoe, Ont.—Tenders will be received up till the 7th of July, 1913, for the construction of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

South Edmonton, Alta.—Tenders are being called for the erection of the new C. N.R. station at South Edmonton. The new building will be built of brick and stone, and together with the iron covered freight shed will cost about $40,000.

Toronto, Ont.—Plans are being prepared for the new Dominion Government buildings and Union passenger station to be built between Yonge and York Streets. It is proposed to widen both Front and Yonge Streets to provide ample approach to the new customs and station buildings. This means the removal of the present customs buildings. They will be replaced by a handsome seven-story building, the estimated cost of which will be between a million and a half and two millions. The union station, plans for which are being completed, will cost probably two millions.

Toronto, Ont.—In connection with the proposed construction of a viaduct, the Harbor Commission will make provision for the accommodation for over sixty ocean freighters. None of the slips will be narrower than 200 feet, but a number of those especially required by the coal firms will be considerably larger on account of the amount of machinery required for loading and unloading purposes. The Bay at this point will be dredged to a depth of thirty feet, in conformity with the depth of the Welland Canal. The construction of these extra dockage facilities will entail an expenditure of $5,000,000.

+—Toronto, Ont.—The Dominion Bank has awarded the NATIONAL FIREPROOF COMPANY the contract for the tile floors and fireproofing for the new building. The contract price is not given.

▲—Valleyfield, Que.—Tenders will be received up till the 18th of July, 1913, for the construction of a protection for the Government dam. Plans and specifications may be obtained from Chief Engineer, Ottawa, Supt. Engineer, Quebec, Canals, Montreal and the Department of Railways and Canals, Ottawa. L. K. Jones, secretary.

Tarvia

Preserves Roads
Prevents Dust~

Atwater Avenue, Montreal, Quebec. Constructed with Tarvia Modern Pavement

Tarvia vs. Plain Macadam

THE right-hand side of the above roadway was built with "Tarvia X." The left-hand side is plain macadam. The tarviated side is adequate to cope with the traffic. The plain macadam side is in persistent disrepair.

In previous years this roadway washed and gullied very badly in the spring and many tons of macadam were dislodged from different parts of this hill and deposited at the bottom by the spring rains.

Now, after a rain, the tarviated side drains quickly and easily to the gutter. The plain macadam side gets muddy and stays so for some time.

The tarviated side gets more than its share of the traffic because it affords superior traction, yet it is free of dust except for what is blown upon it from its dusty neighbor on the other side of the tracks.

As to maintenance, the tarviated side needs no attention, while the plain macadam is in frequent need of care. The cost of upkeep in the long run will be considerably greater for the plain macadam, and the results will be very inferior.

The initial cost of the plain macadam may have been a little lower, but the high maintenance more than wipes out the saving.

"Tarvia X" which was used on half of this road is a dense, viscid coal tar product which is immune from damage by water and frost. It forms a dense, plastic matrix about the stone, prevents internal movements of the roadway, and by reason of its plasticity, develops a surface that grows smoother with traffic.

THE PATERSON MANUFACTURING COMPANY, LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED

ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

BRIDGES, ROADS AND PAVEMENTS.

Halifax, N.S.—Tenders will be received up till the 9th of July, 1913, for the construction of smaller bridges and culverts in the county of Halifax. Plans and specifications may be obtained from E. H. Armstrong, Commissioner of Public Works and Mines, Halifax, N.S.

+—Jacksonville, Florida.—The city has awarded the DOLARWAY PAVING COMPANY the contract for the construction of 26,141 square yards of Dolarway pavement.

▲—Oakville, Ont.—Tenders will be received up till the 10th of July, 1913, for the construction of 12,800 square yards of armoured, reinforced concrete pavement and 9,000 lineal feet of curbing. Plans and specifications may be obtained from J. A. Bell and Son, St. Thomas, and C. H. Cross, chairman Streets Committee.

Peterborough, Ont.—City Engineer Parsons has been authorized to advertise for tenders for paving with bitulithic pavement, to cost $30,084. The Hunter section will be paved with concrete as an experiment; the pavement will be laid a grade lower than George Street, so that it may be topped with bitulithic or some other material should the concrete not stand the wear and tear.

▲—Regina, Sask.—Tenders will be received up till the 9th of July, 1913, for the construction of 500,000 square feet of concrete sidewalk. Plans and specifications may be obtained from City Engineer F. McArthur, City Commissioners, L. A. Thornton, J. A. Reed and J. Martin, mayor.

+—Saanich, B.C.—The Council have awarded the following contracts for paving:—The WORSWICK PAVING COMPANY will pay, according to their tender, 95 per cent. for the municipal bonds, will lay the paving at $1.715 with a five years' guarantee, or at $1.87 with a ten years' guarantee; wooden margins $51 per 1,000 feet, and crushed rock or gravel binder at 98 cents per square yard. The WARREN CONSTRUCTION COMPANY will pay 95 per cent. for the municipal bonds, will lay the pavement at $1.725 per yard with five years' guarantee, or for $1.825 with ten years' guarantee, wooden margins, $50 per 1,000 feet, and crushed rock or gravel binder, 97 cents per yard. The prices of the competitive tenderers were contained in the issue of June 26th of *The Canadian Engineer.*

▲—Saskatoon, Sask.—Tenders will be received up till the 15th of July, 1913, for the construction of a concrete bridge over the South Saskatchewan River. Plans and specifications may be obtained from the Board of Highway Commissioners. A. J. McPherson, chairman.

▲—Saskatoon, Sask.—Tenders will be received up till the 21st of July, 1913, for supplying boulevard posts. Specifications may be obtained from Mr. E. Harrison, City Electrical Engineer, and the Board of Commissioners. F. E. Harrison, chairman.

▲—Toronto, Ont.—Tenders will be received up till the 7th of July, 1913, for the construction of a concrete beam bridge over the Humber River. Plans and specifications may be obtained from Frank Barber, township engineer.

▲—Toronto, Ont.—Tenders will be received up till the 7th of July for the construction of concrete abutments for concrete bridge over Grand River, Township of Amaranth. Plans and specifications may be obtained from Frank Barber, township engineer.

▲—Toronto, Ont.—Tenders will be received up till the 7th of July, 1913, for the construction of the abutments for the Eckardt Bridge. Plans and specifications may be obtained from Frank Barber, Bridge Engineer and E. A. James, Chief Engineer of the Highway Boards.

+—Toronto, Ont.—Messrs. CARLYLE AND SONS have been awarded the contract for bridge construction in the county of York. The contract price is $3,100. Frank Barber, County Engineer.

The by-law to provide for the extension of the Orillia waterworks system, concerning which a call for tenders appeared in June 19th issue of *The Canadian Engineer*, met with defeat at the hands of the ratepayers. It is understood that the town will take another vote upon the question in a short time.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending June 16th, 1913:—

A Nova Scotia correspondent interested in Labrador sawmill, with a capacity of 100 tons of pulpwood per day, is desirous of being placed in communication with buyers in Great Britain.

From the branch for city trade inquiries, 73 Basinghall Street, E.C.

A Yorkshire manufacturer of stationary steam engines wishes to arrange for their sale in Canada.

A Lincolnshire company manufacturing a specialty in pig iron desire correspondence with Canadian importers.

A London company manufacturing oxy-acetylene welding and cutting plants are desirous of opening up in Canada.

A North of Englaud company manufacturing cast iron spigot and socket pipes wish to arrange for their sale in Eastern Canada.

A Sheffield company manufacturing steel in bars and sheets, castings and forgings, also a large variety of light and heavy edge tools, etc., are about to send out a representative to Canada, and would be pleased to hear from responsible Canadian firms who would be prepared to act as their resident agents.

A London importer asks to be placed in communication with Canadian producers and shippers of ores (iron, nickel, copper, silver, gold, etc., who seek export trade.

A Glasgow firm desires the addresses of Canadian manufacturers of tar, of which they are seeking supplies.

An Ottawa firm recently organized for the purpose of handling engineering supplies and machinery would be glad to hear from United Kingdom manufacturers of motors, metal working machinery, wood-working machinery, etc., seeking Canadian representation.

A Canadian company producing mica upon a large scale ask to be placed in communication with United Kingdom dealers, more particularly with buyers of ground amber mica.

The following inquiries have been received relating to Canadian trade: 602.—A mining engineer residing in Berlin is prepared to transact business and to act as agent or representative for mining and engineering firms and metallurgical works. Reports on mineral deposits and properties undertaken, or existing reports revised and translated for intending continental investors. Agent sale or financing of mineral or industrial propositions. Patent agency and representation. 605.—A Newfoundland firm desires communication with a Canadian manufacturer of interlocking rubber tiling. 610.—A London company manufacturing belting, hose and tubing, valves, hydraulic rings, washers, etc., from a special material, wish to appoint reliable resident firms as agents for the sale of their products in the principal Canadian cities. 611.—A Glasgow firm desire the addresses of Canadian manufacturers of tar, of which they are seeking supplies. The names of the firms making these inquiries, with their addresses, can be obtained upon application to: The Inquiries Branch, the Department of Trade and Commerce, Ottawa, or the secretary of the Canadian Manufacturers' Association, Toronto, or the secretary of the Board of Trade at Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary and Chambre de Commerce du District du Montreal.

ILLUMINATING ENGINEERING SOCIETY.

The last regular meeting of the section until October was held at the Monadnock Block Auditorium, Western Society of Engineers, Chicago.

A paper was read on "Notes on Postal Car Illumination," by A. J. Severt, Milwaukee, Wis., dealing with the result of a series of tests recently conducted in connection with the lighting of United States Mail Cars.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

19494—June 6—Authorizing Corporation of city of Regina, Sask., to construct its Municipal St. Rly., across Commercial Spur of C.P.R., at intersection of Winnipeg St., and Eighth Ave., at rail level, subject to certain conditions.

19495—June 6—Authorizing city of Regina, Sask., to construct Municipal St. Rly. across Commercial Spur of C.P.R., at rail level, on North Railway St., on Dewdney Ave., Regina, subject to certain conditions.

19496—May 30—Granting liberty to C.N.R. to remove spur serving lots 23 and 33, part of Block 1, D.G.S., Lot 1, Parish of St. John, Plan 129, owned by W. A. Taylor.

19497—May 15—Dismissing application of Kelowna Board of Trade, B.C., for Order directing C.P.R. to discontinue charge of $1 made on all incoming and outgoing cars delivered from and taken to its car barges.

19498—June 6—Directing G.T.P. Ry., at its own expense, to provide and construct cattle pass 14 ft. wide and 7 ft. high, under its railway, and two farm crossings, at points on farm of Fred. W. Green, of Moose Jaw, Sask., to be agreed upon between the parties.

19499—June 5—Authorizing Esquimalt and Nanaimo Ry. Co. to construct bridge No. 30.4 over Tsable River, Comox Extension; B.C.

19500—May 29—Directing C.P.R. to move to west of Government Road Allowance all portions of its tracks on south side of main line, passing track switch to be located not closer than 500 ft. from west side of Government Road Allowance; no cars be left standing closer than 450 ft. from said road on Commercial or Elevator tracks, or 500 ft. on Mill or Spur track, etc., and rescinding Order No. 18613, dated Feb. 1st, 1913.

19501—June 7—Authorizing C.P.R to construct spurs for Builders' Supply Co., Limited, of Winnipeg, Manitoba.

19502—June 6—Authorizing city of Regina, Sask., to construct its Municipal St. Rly. across Commercial Spur of C.P.R. at rail level, on Dewdney Ave., immediately west of Broad St., subject to certain conditions.

19503—June 5—Authorizing C.N.O.R. to construct undercrossings on farm of J. J. Stinson and Robert Moore, at stations 667.80 and 668.10, Lots 11 and 12, Con. 2, Tp. Nepean, Ontario .

19504—May 14—Authorizing Lake Erie and Northern Ry. Co. to construct across G.T.R. Co.'s 17th District Main Line between Paris and St. George, Ontario, at Station 538.16.9. by means of an undercrossing.

19505—May 12—Authorizing Lake Erie and Northern Railway Company to construct across Six (6) highways in Tp. South Dumfries, Ontario.

19506—June 7.—Authorizing city of Regina, Sask., to construct Municipal St. Rly. across C.N.R. at rail level, on Fourth Ave., between McIntyre and Lorne Streets, Regina, subject to and upon certain conditions.

19507—June 6—Authorizing city of Regina, Sask., to construct Municipal St. Railway across G.T.P. Branch Lines Company, at rail level, at intersection of Elphinstone Street, immediately north of Sixteenth Avenue to station of said company, Regina, subject to certain conditions.

19508—June 6—Authorizing city of Regina, to construct Municipal St. Rly., across C.N.R., at rail level, on Albert St., where Rly. intersects Albert between Chicago and Washington Avenues, subject to and upon certain conditions.

19509—June 6—Authorizing city of Regina to construct Municipal St. Rly., across G.T.P. Branch Lines Co., where same crosses Fifth Ave., between Ross and Parliament Sts., Regina, Sask., subject to certain conditions.

19510—June 6—Authorizing city of Regina to construct Municipal St. Rly. across G.T.P. Branch Lines Co., at rail level, where same intersects Thirteenth Ave., between Ross and Allan Sts., Regina, Sask., subject to and upon certain conditions.

19511—June 6—Authorizing C.N.R. to construct across and divert public road between Secs. 12 and 13, Tp. 6, R. 18, W. 2 M., Sask.; and after diversion is made and grade crossing constructed company may close portion of present road allowance to be diverted within limits of its right-of-way.

19512—June 9—Establishing the collection and delivery limits of the Dominion Express Co., in the city of Kelowna, B.C.; and rescinding Order No. 16514, dated May 14th, 1912.

19513—June 7—Directing that Esquimalt and Nanaimo Ry. Co. construct steel span girder bridge, with clearance of 14 ft., and a width between abutments of 40 ft. upon and over Hereward Rd., Victoria, B.C.; work to be done within 6 months from date of this Order; city of Victoria to do work of re-grading highway; cost of construction of bridge be apportioned as follows;—20 per cent. out of "The Railway Grade-Crossing Fund," the remainder as follows:—one-third by Rly. Co., and two-thirds by Applicant, (Mun. Council of Corporation of city of Victoria, B.C.).

19514—June 9—Directing that G.T.R. operate trains over crossing of Queen St., village of Mount Forest, Ont., at a speed limit not exceeding 10 miles an hour: all switching movements on siding to be flagged over said crossing.

19515—June 9—Dismissing application city of Calgary, Alta., for an Order extending express delivery limits in said city, authorized under Order No. 15149, dated September 8th, 1911.

19516—June 7—Approving plans showing proposed new piers of St. Francois River bridge, between St. Francois du Lac and Pierreville, P.Q., on Quebec, Montreal and Southern Ry.

19517—June 9—Authorizing Toronto Suburban Ry. Co., to connect with C.P.R., at Cooksville, Lot 12, Con. 1, north of Dundas St., Tp. Toronto, Co. Peel, Ontario.

19518—June 9—Authorizing C.N.O.R. to construct across public road between Lots 3 and 4, Con. 3, Tp. York, Ontario.

19519—June 9—Authorizing C.N.O.R. to divert public road on Lot 11, Con. 1. Tp. Pembroke, Co. Renfrew, Ont., and to construct across same by means of structure carrying railway over highway.

19520—June 9—Directing the form of bond required to be given the municipality, of the village of New Toronto, by the G.T.R., in connection with the laying of an additional 6-inch water main 4 ft. below surface of ground, for purpose of conveying water from Lake Ontario to G.T.R. terminals at New Toronto, across Lake Shore Road, under track of Toronto and York Radial Ry. Co., along 6th St., and across New Toronto St., as authorized by Order No. 18794, dated February 26th, 1913.

19521—June 9—Authorizing C.P.R. to operate bridge No. 0.55 to Sortin, Smith's Falls Subdivision, Eastern Div., Ontario, and Bridge No. 1.85, Montreal Terminals Bethune, Ave., Subway, city of Westmount, Quebec.

19522—June 9—Authorizing C.P.R. to operate bridge No. 140.5, Calgary Subdivision, and bridge No. 96.6, Calgary Subdivision.

19523—June 7—Authorizing C.P.R. to construct extension of said storage siding across road diversion in Lot 21, Con. 13, Tp. of Medonte, Co. Simcoe, Ontario, at mileage 74.87, by means of a grade crossing.

19524—June 9—Authorizing C.P.R. to construct spur for Regina Trading Co., Limited, Regina, Saskatchewan.

19525—June 9—Authorizing C.P.R. to construct spur for Rumely Products Co., Inc., Regina, Saskatchewan.

19526—June 9—Authorizing Esquimalt and Nanaimo Ry. Co. to construct bridge No. 25.0 over Rosewell Creek, Comox Extension, B.C.

19527—June 9—Amending Order No. 19319, dated May 15th, 1913, by striking out paragraph 4 in operative part of said Order and substituting therefor the following: "4. That the conductors of Applicant's cars operate the said half-interlocking plant."

19528—June 9—Directing G.T.R. to install improved type of illuminated electric bell at crossing known as Fort Erie and Port Colborne Road, east of Sherkston Station; 20 per cent. of cost of installing bell be paid out of "Railway Grade-Crossing Fund," remainder by Railway Company.

19529—June 9—Directing that cost of constructing subway under C.P.R. at Hunter and Bexley Sts., Woodstock, Ont., authorized under Order No. 16986, dated July 8th, 1912, be apportioned as follows: 20 per cent. out of "The Railway Grade-Crossing Fund," and the remainder by Railway Company.

19530—June 9—Establishing collection and delivery limits of express companies in city of London, Ontario.

19531—June 9—Establishing collection and delivery limits of Dominion Express Company in town of Taber, Alberta.

19532—June 9—Establishing collection and delivery limits of express companies in city of Sault Ste. Marie, Ont., and a portion of adjoining town of Steelton.

19533—June 9—Establishing collection and delivery limits of express companies in city of Windsor, Ont.

19534—June 9—Establishing collection and delivery limits of express companies in town of Walkerville, Ontario; and rescinding Order No. 15399, dated October 24th, 1912.

19535—June 4—Authorizing G.T.R. to construct sidings and additional tracks, or yard extensions, to and into premises of Canadian Furnace Company, village of Port Colborne, Ontario.

19536—June 10—Requiring C.P.R. to operate two first-class trains, each way, per day, on week days, between Ottawa and Prescott; time of run to be not more than two hours; this Order to be made effective 1st day of July next. Railway Company is restrained from hauling freight on said trains.

19537—June 9—Establishing collection and delivery limits of express companies in city of St. Thomas, Ontario.

19538—June 9—Establishing collection and delivery limits of express companies in town of Haileybury, Ontario.

19539—June 9—Extending eastern and southern limits of area within which railway companies undertake the cartage of freight in city of London, Ontario, at toll therefor published and filed.

19540—June 10—Refusing application of Dominion Townlots, Limited, for authority to construct a highway across C.P.R. at Broadway, Saskatchewan, near present farm crossing, in N.½ Sec. 16-17-19, W. 2. M.

19541—June 10—Authorizing Esquimalt & Nanaimo Ry. Co. to divert Comox waggon road to connect with public road crossing its railway at mileage 13.0 on its Comox Extension, B.C.; and rescinding Order No. 9843, dated March 10th, 1910.

19542—June 10—Authorizing G.T.R. to reconstruct bridge No. 134 at mileage 222.32, 2nd Dist., carrying railway over St. Francis River, near Richmond, Quebec.

19543—June 10—Authorizing C.P.R. to construct bridge No. 10.8 over South Spitler Creek, Port Burwell Sub. Div., near Ostrander Station, Ontario.

19544—June 10—Directing C.N.R. to construct suitable culvert under its tracks on Winchester Ave., municipality of Fort Garry.

19545—June 10—Directing C.N.R. and C.P.R. to deepen culverts under their tracks 3 feet, as well as ditches across their respective rights of way, with exception of that portion of C.P.R. right of way which provides roadway to station buildings at village of Maryfield, Sask.; culvert at this point to be lowered 1 foot; ditch to and from railway companies' right of way to be lowered by complainant (village of Maryfield, Sask.); work to be completed by August 15th, 1913.

19546—June 10—Authorizing Hamilton Street Rly. to construct two tracks on its railway, at grade, across T. H. & B. Rly. at intersection of Main and Trolley Sts., Hamilton, Ont., subject to and upon certain conditions.

19547—June 10—Authorizing C.N.O. Rly. to construct across public road between townships Pembroke and Stafford, Co. Renfrew, Ont., by means of structure carrying railway over highway.

19548—June 10—Authorizing C.N.R. to construct, at its own expense, across six (6) highways in province of Saskatchewan.

19549—June 10—Extending until June 30th, 1913, time within which G.T.R. installs bell at crossing of first highway, 150 feet west of St. Hilaire Station, Quebec.

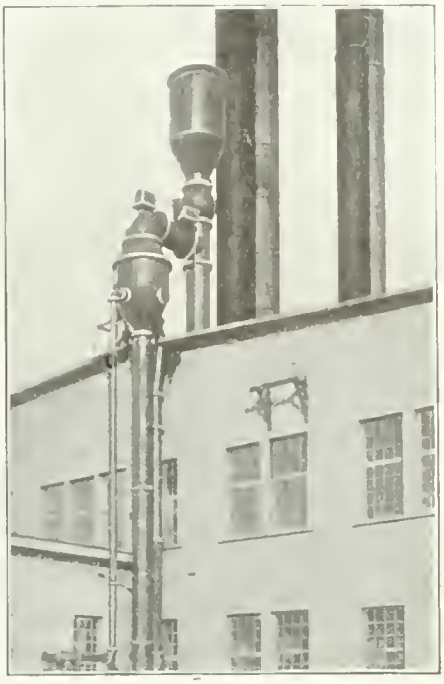
19550—June 7—Authorizing G.T.R. to construct siding for J. B. Mustard, on Lot 16, Con. 1, Tp. Stanley, Co. Huron, Ontario.

19551—June 10—Authorizing C.P.R. to cross, temporarily, with its Bergen North Easterly Cut-off the C.N.R. Co.'s Oak Point Branch; crossing to be protected by watchman, at expense of applicant company (O.P.R.).

CONDENSING APPARATUS

specially designed to secure

GREATER STEAM ECONOMY



WORKS: WILLIAM and SEIGNEURS STREETS, MONTREAL

THE JOHN McDOUGALL CALEDONIAN IRON WORKS CO., Limited

Manufacturers of Boilers, Castings, Condensers, Elevators, Engines, Filters, Forgings, Hydraulic Machinery, Pumps, centrifugal and reciprocating, Steam Turbines, Tanks, Water Wheels, Water Works Plants.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction of the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

Sterilization Co.

Union Building, Clinton Street

NEWARK, N.J.

Also engineers for the electrolytic treatment of water.

A Perfect Weir Gage

Carries an unusually large card and will register without any reduction through a variation of two feet or on a two to one reduction through a variation of four feet.

Can be applied anywhere where fluctuation is within limit named and where great accuracy is desired.

In use on weirs, sewage disposal plants, irrigation and stream gaging.

Hydro Manufacturing Co.

700 BULLITT BUILDING, PHILADELPHIA, Pa.

19552—June 10—Authorizing C.P.R. to construct spur for Messrs. R. MacFarlane & Co., Limited, Montreal, Quebec.

19553—June 12—Dismissing application of Harry Simpson and others of Niverville, Manitoba, for an Order directing C.P.R. to stop express trains travelling in both directions, at station at Niverville, on Emerson Branch of C.P.R.

19554—June 10—Directing C.N.R. to place station agent at D'Arcy, Saskatchewan, on or before August 1st, 1913.

19555—June 11—Directing that crossings of highways by C.N.R., known as Central Ave., and First Ave. East, City of Prince Albert, Sask., be protected by watchmen between 6.30 a.m. and 6.30 p.m. daily, except Sunday; cost of maintaining said watchmen be apportioned as follows: Two-thirds be borne by C.N.R. and one-third by city; payment be made monthly, or quarterly, as parties may agree; any dispute between parties to be settled by the Board.

19556—June 10—Authorizing C.P.R. to construct diveraion of roadway in Lot 6616, Kootenay District, B.C., at mileage 46.7, from Colvalli, on its Cranbrook Sub. Div., B.C., and construct tracks of said line across said diversion, by means of a grade crossing.

19557—June 11—Authorizing C.P.R. to construct diversion of road allowance in Sec. 35-19-19, W. 3 M., Sask., at mileage 38.44 from Swift Current, on Swift Current Northwesterly Branch; and construct, by means of grade crossing, tracks across said diversion (of said Swift Current Northwesterly Branch).

19558—June 11—Authorizing C.P.R. to divert and construct across diversion of road allowance in Sec. 36-19-19, W. 3 M., Sask., on its Swift Current Northwesterly Branch, by means of a bridge.

19559—June 12—Authorizing C.L.O. & W. Ry. (C.P.R.) to divert highway between Lots 24 and 25, Con. "A," Tp. Brighton, at mileage 94.15 from Glen Tay, so as to cross C.L.O. & W. Ry. and G.T.R. at mileage 94.41 from Glen Tay; and construct its tracks, by means of grade crossing, over new road at mileage 94.41.

19560—May 30—Authorizing C.P.R. to construct main line tracks and sidings of Island Sub. Div., B.C. Division, across Franklyn St., Lubock Square and Fitzwilliam St., city of Nanaimo, B.C.

19561—June 12—Amending Order No. 18927, dated March 27th, 1913, by striking out words "and future protection," in second last line of operative part of said Order.

19562—June 12—Extending, until July 19th, 1913, the time within which G.T.R. install electric bell at crossing of Clara St., near Glen Robertson Station, Ontario.

19563—June 12—Directing C.N.R. to reconstruct shelter building at Wroxton, Sask., so as to afford accommodation equal to standard third class station; work to be completed before Sept. 15th, 1913, and rescinding Order No. 19201, dated May 3rd, 1913.

19564—June 11—Directing G.T.R. to employ a night, as well as a day, watchman at crossing of Hurontario St., Port Credit, Ont., between 7 p.m. and 7 a.m.; expense of maintaining said watchman be apportioned as follows: 80 per cent. by G.T.P. and 20 per cent. by Tp. Toronto.

19565—June 12—Approving location C.N.O.R. station grounds at Galea, Tp. Field, Dist. Nipissing, at mileage 259.30 from Ottawa.

19566—June 12—Extending, until July 15th, 1913, time within which C.N.R. erect gates at crossing of Frederica and Edward Sts., city of Fort William, Ontario.

19567—June 11—Authorozing C.P.R. to construct spur for Massey-Harris Co., Calgary, Alta.

19568—June 12—Directing C.N.R. to install, within 60 days from date of this Order, an improved type of automatic electric bell at crossing of highway between Lots 2 and 3, Con. 4, at Station 2661, Tp. Scarboro, Co. York, Ontario; Railway Company to bear and pay expense of installing and maintaining said bell.

19569—June 11—Authorizing C.P.R. to construct, by means of a grade crossing, tracks of Johnville Ballast Pit spur across public road between E. ½ of Lot 27, Rge. 3 and Lot 27-D, Rge. 2, Tp. Eaton, Co. Compton, Quebec.

19570—June 13—Directing that where shippers furnish slats for floors of refrigerator cars not equipped with permanent slatted or double floors, for carriage of fresh fruits (apples excepted) under refrigeration, railway companies subject to jurisdiction of Parliament of Canada shall allow shipper $3 per car for said slatting; shipper be permitted to deduct said allowance from freight charges payable by him upon shipment in such car; shipper's receipt for amount so allowed be given railway company's agent at forwarding station, and be accepted by him as so much cash in prepayment of freight charges on such car.

19571—June 12—Directing C.P.R. to construct spur shown in red on plan on file with Board under file No. 22135, from point marked "B" to east boundary of Canada Tile & Fireproofing Co., Ltd., property; that C.N.R. construct spur from point marked "D" to southern boundary of said property; spurs to be completed within three months from date of this Order.

19572—June 14—Approving, subject to terms of agreement, plan showing proposed location of temporary chain hoist and raised rail, for purpose of unloading supplies in connection with St. Clair Ave. civic car lines near Davenport Station of G.T.R., Toronto, Ontario.

19573—June 16—Authorizing C.N.O.R. to construct across Kathleen St., town of Sudbury, within 60 days from date of this Order, C.N.O.R. install improved type of automatic electric bell at said crossing, and thereafter maintain bell at its own expense.

19574—June 16—Authorizing Algoma Eastern Ry. Co. to construct Goat Island Coal Handling Bridge, on Goat Island Docks, near Little Current, Ontario.

19575—June 16—Authorizing Esquimalt & Nanaimo Ry. Co. to construct Bridge No. 27.8 over Coal Creek, on Comox Extension, Dist. Newcastle, Vancouver Island, B.C.

19576—June 16—Approving change or altheration in C.L.O. & W. Ry. Co.'s line of railway; in Lots 23, 24 and 25, Con. A, Tp. Haldimand, Ont.

19577—June 12—Authorizing C.P.R., subject to conditions contained in by-law and agreement, to construct extension of railway across certain lands, streets and lanes in city of Edmonton, Alta.

19578—June 16—Authorizing C.P.R. to construct diversion of road allowance in N.E. ¼ of Sec. 19-17-24, W.P.M.; after such diversion company may close portion of road allowance between S.E. ¼ of Sec. 30 and N.E. ¼ of Sec. 19-17-24, W.P.M., within limits of right of way, mileage 44.47 at Kelloe, on its Bredenbury Sub. Div., Manitoba Division.

19579—June 16—Authorizing G.T.R. to reconstruct bridge No. 23, at Mile Post 47.28 on 21st District of its railway, 1¼ miles south of Hickson, Ont., over private roadway and stream.

19580—June 12—Authorizing G.T.R. to construct siding for A. Davis & Son, Ltd., Kingston, Ontario.

19581—June 12—Authorizing G.T.R. to construct siding, and spur therefrom, for the Dominion Tire Co., Ltd. (Canadian Consolidated Rubber Co.), city of Berlin, Ontario.

19582—June 12—Authorizing G.T.R. to construct two additional sidings to and into premises of C. A. Scott, on part Lot 2, south of Carlaw Ave., Toronto, Ontario.

19583—June 16—Approving and authorizing clearance as shown on G.T.R. plan showing clearance at its new bonded freight house on Wellington St., Montreal, Quebec.

19584—June 16—Authorizing C.N.R. to construct spur for city of Saskatoon, Sask., crossing Avenue "T" in said city.

19585—June 17—Recommending to the Governor-General in-Council for sanction an agreement, dated June 2nd, 1913, amalgamating the C.N.R. and Can. Nor. Branch Lines Co.

19586—June 16—Approving plans and specifications of Pennington Drain, under G.T.R., on line between Lots 2 and 3, Tp. South Norwich, Co. Oxford, Ont.; railway company to have option of doing work on its right of way.

19587—June 17—Approving location G.T.P. Branch Lines Co.'s station at Cando, Sec. 22-39-16, W. 3. M., Battleford Branch, Sask.; station to be in accordance with company's Standard Structural Plan No. 1, on file with the Board.

19588—June 17—Approving locations of G.T.P. Ry. stations as follows: No. 1, mileage 1155.6 west of Winnipeg, Cariboo District; and No. 2, mileage 1147.2 west of Winnipeg, Cariboo District, B.C.

19589—June 16—Approving location G.T.P. Branch Lines Co.'s station, at Fort, in Sec. 28-33-19, W. 3 M., on Biggar-Calgary Branch, Sask.; station to be in accordance with company's Standard Structural Plan No. 1 on file with the Board.

19590—June 17—Authorizing G.T.P. Branch Lines Co. to carry traffic on Biggar-Calgary Branch between Biggar (mileage 0.0) and Dodsland (mileage 48.0), Alta., provided speed of trains be limited to a rate not exceeding 20 miles an hour; and rescinding Order No. 17850, dated October 24th, 1912.

19591—June 16—Authorizing C.L.O. & W. Ry. (C.P.R.) to construct road diveraion in Lot 25, Con. 1, Tp. Clarke, Co. Durham, Ont., at mileage 142.05.

19592—June 16—Approving and authorizing clearances as shown on C.P.R. plan showing clearance of tracks of its coaling plant in North Tranacona Yards, Manitoba.

19593—June 17—Authorizing C.P.R. to construct bridge No. 103.7 (near Foster Station), on Sherbrooke Sub. Div., Eastern Div., P.Q.

19594—May 19—Authorizing C.P.R. to construct spur to Hastings Park, Vancouver, B.C.; spur to be constructed within three months from date of this Order.

19595—June 16—Authorizing C.P.R. to construct new trackage in railway yard, North Transcona, Man., across transmisaion line of city of Winnipeg, in Lot 58, Kildonan.

19596—June 17—Extending, until August 15th, 1913, time within which C.P.R. install gates at North Vancouver Ferry, Columbia Ave., and G.T.P.R. Co.'s team crossings, Vancouver, B.C.

19597—June 17—Authorizing C.P.R. to construct, by means of grade crossings, its Ballast Pit Spur across two (2) highways, namely, mileage 0.74 between Lot 8, Con. 1 and Lot 8, Con. 2, and at mileage 0.38, in Lot 9, Con. 2, Tp. Hinchinbrooke, Co. Frontenac, Ontario.

19598—June 16—Directing C.N.R. to erect a third-class station at Decker, Man., and construct two-car cattle pen at said point; work to be completed by Sept. 15th, 1913.

19599—June 16—Directing C.P.R. to move station off public road allowance, to a point 300 ft. west, and construct proper crossing along line of existing highway, municipality of Rosedale, to move grain elevators off highway, at Franklin, Man.; work to be completed within 60 days from date of this Order.

19600—June 17—Authorizing Dominion Atlantic Ry. Co. to construct siding for Markland Fruit Co., Ltd., across public road at Kingston, King's County, Province of Nova Scotia.

19601—June 17—Authorizing G.T.R. to construct certain spurs into premises of Pilkington Bros., Ltd., on Lots 71 and 72, Tp. Thorold, County of Welland, Ontario.

19602—June 17—Authorizing C.P.R. to construct spur for J. R. Johnston, Medicine Hat, Alta., to be completed within three months from date of this Order.

19603—June 17—Authorizing C.N.R. to construct spur along lane through Blocks 21 and 31, to cross Isabella St., Saskatoon, Sask., with said spur; and to construct spur along lane through Block 30, in said city.

19604—June 12—Directing that all wires at Yonge St. and Avenue Road, North Toronto, be placed underground, excepting long distance wires of Bell Telephone Co. Each company bear and pay cost of moving its wires on said streets.

19605—June 16—Authorizing C.L.O. & W. Ry. (C.P.R.) to operate work train service over crossing of its railway with C.N.O.R., for period of six months from date of this Order, pending completion of interlocking plant: provided that during such operation crossing be protected by flagman maintained at C.L.O. & W. Ry.'s expense.

19606—June 13—Relieving C.P.R. from providing further protection at crossing of first highway east of Berthier Jct., Que.

19607—June 16—Directing C.P.R. forthwith to remove trees south of track and west of crossing, at mileage 71.2, about three (3) miles west of Pointe du Lac Station, Quebec.

19608—June 12—Authorizing C.P.R. to construct spur adjoining Neebing Ave., city of Fort William, beginning at a point on its main line, at mileage 3.14, and extending to a point 100 feet south of main line of C.N.R. to a connection with industrial spur.

19609—June 13—Approving location G.T.R. station at Rideau, Ont., about 400 feet east of Kingston and Ottawa Road.

19610—June 11—Authorizing C.N.O.R. to construct across certain highways in town of Sudbury, Dist. Sudbury, Ontario.

19611—June 18—Approving location G.T.P. Branch Lines Co. station on Regina Boundary Branch, at "Boundary Line," in Sec. 6-1-2, W. 2 M, at mileage 154.8, Saskatchewan.

MACK

The Unit Type Body Which Can Be Discharged—

in sections for carrying coal, wood, cement or building material in different compartments is becoming popular in the building and contracting industries.

We show here a 4-ton Mack Truck of the unit type of body, each compartment of which holds a ton of material. These sections are operated individually which makes this type of dumping body especially adapted for use by coal dealers, building supply dealers, grain dealers, contractors, and all concerns delivering portions of a load to different places.

This view shows a 4-ton Mack Truck, each compartment of which holds a ton of material.

This truck has been delivering on an average of forty loads daily, within a radius of fifteen miles of the City of Hagerstown, Md., making approximately forty miles daily, and has displaced four teams and two men.

MACK

"Leading Gasoline Truck of the World"

The owner advises us that his truck averages seven to eight miles per gallon of gasoline.

The operator was one of their factory hands, whom our expert instructor taught how to manipulate the car, he having had no previous experience in running motor trucks.

We shall be pleased to give you further information on this special kind of Dumping Device.

Mack Trucks are built in 1, 1½, 2, 3, 4, 5, and 7½ tons capacity, with any load distribution and any style of body.

Mack Trucks have proven their reliability, economy and long life by 12 years of real service in every line of transportation.

Send for literature and transportation data on your line of business.

PLANS AND SPECIFICATIONS ON FILE.

The following plans and specifications are on file for reference only, unless otherwise noted, at the office of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg, Man.:—

BIDS CLOSE	NOTED IN ISSUE OF
16-7—Construction of sewer and water-works, Prince Albert, Sask.	26-6

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

BEAUHARNOIS CANAL.

PROTECTION WORK FOR VALLEYFIELD GOVERNMENT DAM.

NOTICE TO CONTRACTORS.

Sealed tenders, addressed to the undersigned and marked "Tenders for works for protecting the Government dam at Valleyfield," will be received at this office until 16 o'clock on Friday, July 18th, 1913.

Plans, specifications and form of contract to be entered into can be seen in or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Quebec Canals, Montreal, Que.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque for the sum of $3,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 25th June, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—44229.

TENDERS FOR BRIDGE CONSTRUCTION.

Sealed tenders plainly marked as to contents will be received by the undersigned up to noon of Monday, July 7th, 1913, for the construction of a concrete beam bridge over the Humber River at Pine Grove, Township of Vaughan.

Plans and specifications and all necessary information may be seen at the office of the undersigned, 57, Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer.

Toronto, June 24th, 1913.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

TRENT CANAL.

Steel Pontoon Gate Lifter.

NOTICE TO CONTRACTORS.

Sealed tenders, addressed to the undersigned and marked "Tender for Steel Pontoon Gate Lifter, Trent Canal," will be received at this office until 16 o'clock on Tuesday, July 29th, 1913.

Plans, Specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Trent Canal, Peterborough, Ont.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the usual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque for the sum of $1,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Assistant Deputy-Minister and Secretary.

Department of Railways and Canals,
Ottawa, 25th June, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—44228.

CITY OF VICTORIA, B.C.

Sealed proposals will be received at the offices of the Water Commissioner, City Hall, until 12 noon, July 15th, 1913, for the fabrication and laying of about 27½ miles of reinforced concrete pipe and appurtenances on the line of the Sooke Water Supply gravity conduit, and in accordance with the requirements of the general specifications prepared by Wynn Meredith, Consulting Engineer, for such construction, pursuant to the provisions of By-law No. 814, and adopted by the Council.

Plans and Specifications can be seen, and Forms of Tender obtained, at the Sooke Water Supply Office, 1414 Douglas Street, Victoria, B.C.

The lowest or any Tender not necessarily accepted.

C. H. RUST,
Water Commissioner.

Victoria, B.C., June 14th, 1913.

(For further tenders see pages 86 and 88).

Insurance Engineering

We maintain a skilled force of engineers and inspectors to advise in regard to the insurance of industrial undertakings.

We offer our services as consultants to engineers and architects who have charge of industrial construction. We have a thorough knowledge of fire protection and the many matters which govern insurance rating.

Manufacturers are invited to permit us to make an inspection and to let us make suggestions regarding fire protection which will add security and also likely more than pay for themselves through reduced insurance rates.

Insurance may be placed through our firm in the same manner as it would be through other insurance brokerage firms. The service rendered—in most cases without cost to our clients—by our staff of inspectors and engineers, makes it profitable for owners who are placing insurance on industrial undertakings to place the insurance through our firm.

15. Highways and Streets (60 pages)
    Index (73 pages, 15,000 references)

16mo, Morocco, 1200 cuts, 500 tables, 1483 pages.

Price, $5.00 net.

TENDERS CALLED FOR

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on Tuesday, July 8th, 1913, for the construction of the following sewers:—

Lane 1st N. Dale Avenue, Glen Road to East End.
Columbine Avenue, Rainsford Road to Kingston Road.
Columbine Avenue, Rainsford Road to Woodbine Avenue.
Jones Avenue, Danforth Avenue to 1,407-ft. North.
Braemore Gardens, Christie Street to Christie Street.
Lane 2nd N. King Street, Princess Street to West End.
Clara Street, Conduit Street to Quebec Avenue.
Beresford Avenue, Bloor Street to North End.
Wheeler Avenue, Queen Street to 1,350-ft. North.
Morley Avenue, 250-ft. S., Gerrard Street to Gerrard Street.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen and forms of tenders obtained at the office of the Commissioner of Works, Toronto.

The tenderers shall submit with their tenders the names of two sureties (approved of by the City Treasurer, not members of the City Council, or officers of the Corporation of the City of Toronto) or in lieu of said securities, the Bond of a Guarantee Company approved of as aforesaid.

The usual conditions relating to tendering as prescribed by City By-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

Toronto, June 26th, 1913.

TENDER FOR BRIDGE ABUTMENTS.

Sealed tenders addressed to R. W. Phillips, secretary of the York Highway Board, will be received up to 6 p.m., Monday, July 7th, 1913, for the construction of the abutments of the Eckardt Bridge, Lot 10, Con. VI., Markham Township.

Plans and specifications may be seen at the office of the Highway Board, or at the office of Frank Barber, Bridge Engineer, 57 Adelaide Street, East, Toronto.

E. A. JAMES,
Chief Engineer to the Board.

Toronto, June 26th, 1913.

CITY OF REGINA.

SIDEWALKS.

Sealed tenders addressed to the City Commissioners, Regina, will be received up until 12 o'clock noon, July 9th, 1913, for the following works:—

Construction of approximately 500,000 sq. ft. of concrete sidewalk.

All information regarding the above may be obtained on application to F. McArthur, City Engineer.

A marked cheque for 5 per cent. of the amount of the bid must accompany each tender.

The city reserves the right to divide the work into two or more contracts, and to reject any or all tenders.

J. MARTIN,
Mayor.
L. A. THORNTON,
J. A. REID.
City Commissioners.

Regina, Sask., June 19th, 1913.

CANADIAN PACIFIC RAILWAY COMPANY.

NORTH TORONTO GRADE SEPARATION.

NOTICE TO CONTRACTORS.

Sealed proposals will be received by the undersigned up to 12 o'clock noon on Saturday, July 12, for the construction of the substructure of a subway to be built at Yonge Street, at North Toronto.

Plans and specifications can be seen at the office of the Engineer of Grade Separation at No. 262 Avenue Road, Toronto, where proposal forms can also be obtained.

B. RIPLEY,
Engineer of Grade Separation.

Toronto, June 26th, 1913.

TENDERS.

CONCRETE BRIDGE AT SASKATOON.

Sealed tenders will be received up to 16.30 o'clock on Tuesday the 15th day of July, 1913, for the under-mentioned work:—

Construction of a concrete bridge over the South Saskatchewan River at Saskatoon.

Tenders for this work must be accompanied by accepted cheque on a chartered bank, or other satisfactory deposit for the sum of $15,000.00 Deposits of unsuccessful tenderers will be returned when contracts are signed.

The right to reject any or all tenders, or to waive any defects or irregularities therein is to be at the discretion of the Chairman of the Highway Commission.

Plans, specifications, forms of tender and all information may be obtained on application to the undersigned.

A deposit of $50 must accompany each request for copy of plans and specifications; this amount will be refunded on the return of plans.

A. J. McPHERSON,
Chairman, Board of Highway Commissioners.

Regina, Saskatchewan, June 20th, 1913.

(The unauthorized insertion of this advertisement will not be paid for.)

CITY OF PRINCE ALBERT, SASK.

Tenders will be received, addressed to the City Clerk, Prince Albert, Sask., until noon, Wednesday, July 16th, 1913, for the following contracts:—

13 D—Laying approximately 22,000 feet of steel water main.
13 E—Laying approximately 25,000 feet of steel water main.
13 F—Laying approximately 26,000 feet of sewers.
13 G—Laying approximately 25,000 feet of sewers.

Plans and specifications are on file at the office of *The Canadian Engineer*, Union Bank Building, Winnipeg, and at the office of the City Engineer, Prince Albert. Instructions to bidders and form of tender may be had on application to the City Engineer. Plans and specifications not to be sent out.

The lowest or any tender not necessarily accepted.

M. H. BAKER,
City Engineer.
N. W. MORTON.
H. E. M. KENSIT,
C. O. DAVIDSON,
City Commissioners.

Prince Albert, Sask., June 23rd, 1913.

(For further tenders see pages 84 and 88).

"STEELCRETE" CONCRETE REINFORCEMENT

for bridge floor slabs, culverts, retaining walls, etc.

Victoria Bridge, Elora, Ont. Messrs. Bowman & Connor (Toronto), Engineers. **"Steelcrete" Floor Reinforcement.**

Slabs of Concrete reinforced with "Steelcrete" Expanded Metal make a permanent bridge floor of the greatest strength, at the least cost, and with the least amount of superimposed dead load on the bridge. In all parts of the world "Steelcrete" is considered the best reinforcement by most bridge engineers. It possesses an absolutely mechanical bond against vibration. It lies flat. Once placed, disarrangement is impossible. The meshes are diamond shaped, the joints absolutely rigid. There are no corrugated or twisted strands. When the load is applied there is no straightening out to split the concrete before the reinforcement comes into tension.

Specify "Steelcrete" for

Floors	Sidewalks	Sewers
Roofs	Foundations	Bridges
Domes	Fortifications	Flumes
Tanks	Warehouses	Tunnels
Dams	Coal Bunkers	Cisterns
Piers	Storage Bins	Subways
Docks	Power Plants	Reservoirs
Vaults	Storage Houses	Conduits
Kilns	Retaining Walls	Factories

ENGINEERS ARE INVITED TO CORRESPOND WITH OUR DESIGNING DEPARTMENT CONCERNING ANY WORK ON HAND.

Tenders Called For

CITY OF SASKATOON.

TENDERS WANTED.

Sealed tenders, addressed to the City Commissioners, Saskatoon, and endorsed "Tender for Boulevard Posts," will be received until 12 o'clock noon on **Monday the 21st day of July, 1913,** for sixty cutter's 5-light Boulevard Posts No. 1121.

Specifications and form of tender may be obtained on application to Mr. E. Hanson, City Electrical Engineer, Saskatoon.

The lowest or any tender not necessarily accepted.

F. E. HARRISON, Mayor,
Chairman of Commissioners.

Saskatoon, Sask., June 25th, 1913.

TO CONTRACTORS.

CONCRETE PAVING, OAKVILLE, ONT.

Sealed tenders addressed to the Chairman of Committee, will be received until noon on **Thursday, the 10th day of July, 1913,** for laying approximately 12,800 square yards of armoured, reinforced concrete pavement and 9,000 lineal feet of curbing.

Plans and specifications can be seen at the Star Office, Oakville, and at the office of J. A. Bell and Son, C.E., St. Thomas.

The committee do not bind themselves to accept the lowest or any tender.

C. H. CROSS.
Chairman Streets Committee, Oakville, Ont.

TENDERS FOR BRIDGE CONSTRUCTION.

Sealed tenders plainly marked as to contents will be received by the undersigned up to 6 p.m., of Monday, July 7th, 1913, for the construction of concrete abutments for concrete bridge over the Grand River, Lot 16, between Concession 5 and 6, Township of Amaranth.

Plans, specifications and all necessary information may be had at the office of the undersigned or seen at the residence of John Bryan, Esq., Laurel, Ont.

Lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer.

57 Adelaide Street East, Toronto, June 24th, 1913.

For further Tenders see pages 84 and 86.

NEW INCORPORATIONS.

Cap St. Martin, Que.—St. Laurent Quarry, $99,800. F. Dufresne, C. LePailleur, St. Laurent; J. A. LePailleur, Lachine.

FOR SALE.—Complete Sewer and Water Contractor's outfit, including one Parsons' Trench Excavator, Trench Braces, Fire Pots, Pumps, etc. For price and terms apply to Navin Bros., Contractors, Moose Jaw, Sask.

$400 WILL BUY a 30 H.P. gas engine and 30 H.P. gas producer; used less than two years on a chopping plant. Israel Brubacker, Elmira, Ont.

INSTRUMENT FACTORY AT MONTREAL.

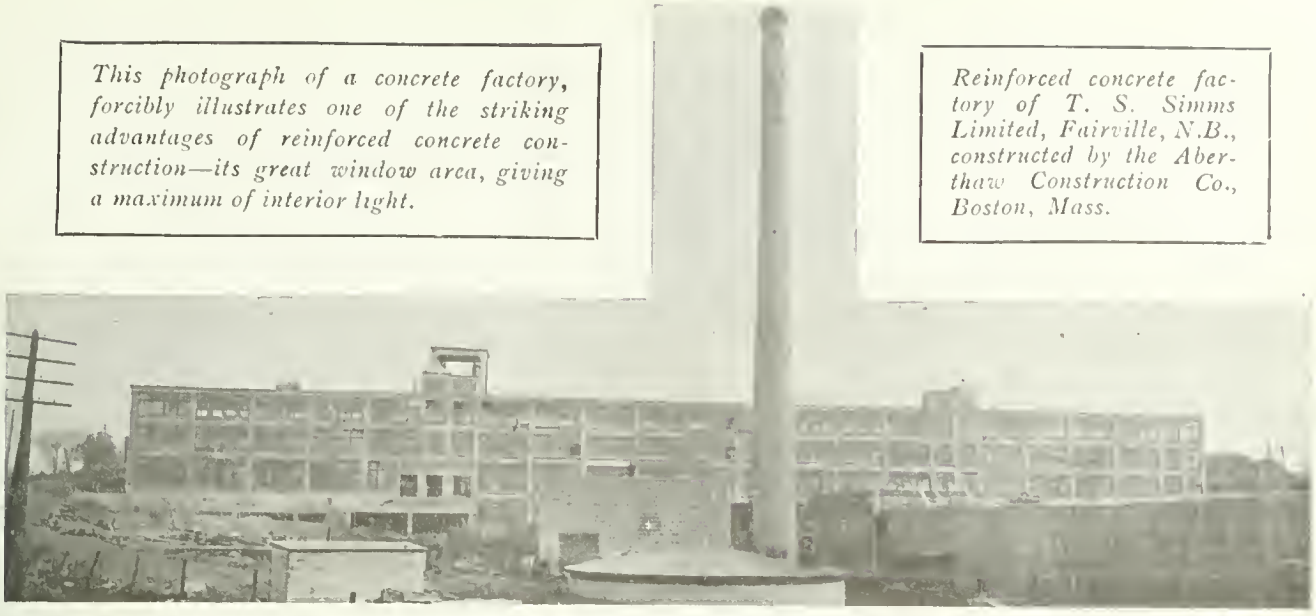
Announcement is made in this week's issue of *The Canadian Engineer* of the opening of a factory at Westmount, Montreal, for the manufacture of scientific instruments. The business has been organized under the name of The Gowlland Company, with Mr. Henry Gowlland as manager. Mr. Gowlland, who had some 30 years of experience in instrument manufacture in England, came to Canada three years ago, at the request of McGill University authorities. The disastrous fire at McGill, which practically ruined most of their instruments, made it imperative that an expert be secured to put the instruments in proper condition. Mr. Gowlland was secured and until comparatively recently was engaged almost solely on McGill's work. Within the past year he found time to do considerable repair work that came to him as a result of his McGill connections, and then he received various requests to build special instruments.

Business along these lines grew so rapidly that Mr. Gowlland decided to open an up-to-date factory devoted exclusively to the manufacture of transits, levels, microscopes, telescopes, heliographs, compasses, sextants and other scientific instruments.

A number of additions to the force at Oshawa headquarters of the Pedlar People, Limited, has recently been made which will further increase the efficiency of the organization. Mr. W. R. Geikie, formerly branch manager for the company in Toronto, will act in the capacity of managing director. Mr. Geikie's thorough knowledge of the business is reinforced by a number of years' experience as a manager of various branches of the Dominion Bank. The operating department has been strengthened by the addition of Mr. W. Loach, formerly connected with the management of Canada Foundries, Limited, Toronto, and with a wide and varied mechanical and manufacturing experience in the United States and Canada. A further addition has been made in the person of Mr. A. T. Enlow, in general charge of sales and advertizing. Mr. Enlow is a steel man of large experience, having been connected with the manufacture and sale of steel in the United States, for the last twenty years. He was plant manager for the United States Steel Corporation, at Cambridge, Ohio, and later sales manager of Berger Manufacturing Company, and general sales manager of the Stark Rolling Mills Company, both of Canton, Ohio.

This photograph of a concrete factory, forcibly illustrates one of the striking advantages of reinforced concrete construction—its great window area, giving a maximum of interior light.

Reinforced concrete factory of T. S. Simms Limited, Fairville, N.B., constructed by the Aberthaw Construction Co., Boston, Mass.



Concrete Factories are Most Efficient

The efficiency of a machine is the ratio of the amount of work a machine does, to the amount of work required to operate it. The output is equal to the input minus the work lost or wasted. The less wasted the greater the efficiency.
In the same way the efficiency of a factory may be defined as the ratio of output to input. Output, financially, is increased by reducing unnecessary expenses.

Concrete Stops Wastes

Concrete buildings are proof against fire, water and vermin. They give the maximum light and are sanitary. They resist vibration, and are permanent and durable.

Fire-proofness reduces insurance rates. Water or liquids used in certain processes will not leak through floors to destroy valuable goods below. Rats and other vermin find no place to live in a concrete building, thus eliminating losses from this cause. Maximum light and sanitary conditions increase efficiency of employees. Lack of vibration reduces wear and tear on machines. Permanency and durability reduce depreciation.

The way in which concrete stops these leaks is fully described in our handsomely illustrated 224 page book, "Factories and Warehouses of Concrete." It contains photographs and data of factories and warehouses for all classes of industries.

POSITIONS VACANT

Advertisements under this heading two cents per word per insertion. Minimum charge fifty cents per insertion.

WANTED.

By the city of Port Arthur, Ontario, **competent Ontario Land Surveyor** to act as Corporation Surveyor. Permanent position for the right man.

Apply giving experience, references and salary expected.

L. M. JONES,
City Engineer.

WANTED.—Experienced detailer and checker on highway bridge work. Applications, care of Box 56, *The Canadian Engineer*, Toronto.

POSITIONS WANTED

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

DO YOU NEED MALE HELP.—Canadian or foreign labor furnished for all classes of work, skilled or unskilled, for office, construction work, waterworks, paving, dams, and wharves. We can put men on the job for you cheaper than you can get them any other way, write or phone for particulars to O'Donnell's Employment Bureau, 116 Wellington Street West, Toronto. Phone Adelaide 3919.

YOUNG CIVIL ENGINEER (26) desires position with engineering firm or contractor. Technical education; six years' experience in city, hydro-electric and railroad survey, highway and concrete construction. Good transitman and draftsman. Have had charge of field and office work for past three years. Excellent references. Have own instruments. Box 42, *The Canadian Engineer*, Toronto.

ELECTRICAL ENGINEER with two years' experience in design, construction and operation of electric light, power street and interurban railways; desires position as engineer, superintendent or foreman. Good references. Change personal reason. Single. Box 44, *The Canadian Engineer*, Toronto.

GRADUATE CIVIL ENGINEERS of long and varied experience in this country and United States, desire work for spare time. Designing, detailing and estimating. Reinforced concrete structural steel a speciality. Box 46, *The Canadian Engineer*, Toronto.

MECHANICAL ENGINEER.—Experienced designer, cost estimator and salesman, works supervision, all kinds of steam engines. Boilers, hydraulic pumps, air machinery and mining plants, seeks position with consulting engineers, contractors, manufacturers or agency business. Highest references, some capital. Box 48, *The Canadian Engineer*, Toronto.

EXPERIENCED MUNICIPAL and sanitary engineer in sewers and sewage disposal works, reinforced concrete and constructional works, (19 years practical experience), desires position with contractor or municipality as superintendent or assistant engineer. Box 52, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER, " '07," with broad experience in designing and detailing steel and reinforced concrete, now employed as designer in Montreal, wishes work during evenings and spare time. Box 54, *The Canadian Engineer*, 628 Transportation Building, Montreal, P.Q.

CIVIL ENGINEER, thoroughly experienced in reinforced concrete design, steel framed buildings, foundations; competent to take full charge of design, estimate, and supervise construction, desires responsible position. Moderate salary. Available on short notice. Box 58, *The Canadian Engineer*, Toronto.

CONDENSED ADVTS

MARKET CONDITIONS

Halifax, July 1st, 1913.

Axes.—Ordinary chopping axes, single bit, $6.50 per dozen; double bit, $11. Special brands, prices on application to jobbers.

Bar Iron.—The market for bar iron is open, but the situation is firm, and prices range as high as $2.35 base.

Black Sheet Iron.—This commodity is in good demand. We quote 24-gauge, $2.60.

Cast Steel.—The market is steady at 10 to 15c., according to makers.

Cement.—Stocks are low and market is steady, $2 per bbl.

Coil Chain.—The jobbing prices of English proof chain in Halifax are as follows:—3-16x4, $7.15; 3-16x3, $6.25; ¼, $5.35; 5-16, $4.60; ⅜, $4.35; 7-16, $4.20; ½, $4; ⅝, $3.65; ¾, $3.50; ⅞, $3.50; 1, $3.50; 1⅛, $3.50.

Fencing Wire.—We quote: plain twisted and galvanized at $3 per 100 lbs.; barb at $2.50 per 100 lbs.; bright staples in 100-lb. kegs at $2.65, and in 50-lb. lots, $3.15. Galvanized staples are 25c. extra.

Galvanized Sheet Iron.—The wholesale prices are as follows: 16 to 20-gauge, $3.85; 22 to 24, $4; 26, $4.50; 28, $4.75. These prices are for less than case lots.

Ingot Tin.—The tin market as usual is a fluctuating one, and the present price is about 60c. net cash.

Lead Pipe.—The price quoted to-day is about $6.65 for the ordinary jobbing quantities.

Linseed Oil.—Raw is fully worth $1.20 and boiled, $1.25 per gallon. Orders are small, the outlook firm, and higher prices looked for.

Nails.—Nails are firm. Wire nails, $2.45, and cut nails, $2.60. Business in this line is reported active.

Peavies.—There is a better enquiry than last year. Prices are unchanged at $11 to $13 per dozen, according to make, but we are advised that there will be an advance.

Pig Lead.—We quote $6.75 for English and $6.50 for Canadian.

Pipe.—Wrought iron, 1-in., $5.25.

Roofing Paper.—The demand is good Tarred paper, $1.70 per 100 lbs.; three-ply, roofing, 90c. per 100 lbs.; two-ply roofing, 65c.; sheathing paper, 30 cents per roll; tarred sheathing, 40 cents per roll.

Rope.—The price of cordage for next spring's supplies is unchanged. For large lots dealers should write jobbers for quotations. Small lots are as follows: Sisal, 9½c. base; lolster rope, 9¾c.; British manilla, 9½c. base; best manilla, 10¾c., base.

Sheet Lead.—The price of sheet lead is also very firm, 3 lbs., and heavier, $6.25 per cwt., in rolls, and $7.25 in smaller quantities.

Steel.—Tire, $2.55; spring, $2.70; machine, $3.25; toe caulk, $3.50; sleigh shoe steel, $2.50; the above are all base prices.

Tin Plates.—I. C. coke, $4.50-$4.75; I. C. charcoal, $5.00; I. X. charcoal, $6.00.

Turpentine.—Prices now quoted are as high as $0.85 in bbls., and $1.05 to $1.15 in smaller quantities. The market is open.

White Lead.—For Canadian pure, in 50 and 25-lb. irons, $7.20 is being asked. Brandram's B.B. genuine in 25, 50, and 100-lb. irons, $7.85, and B.B. No. 1, $6.60.

Zinc.—This commodity is very firm, $8.25 for casks and 9c. pound for smaller quantities. Spelter is 8c. pound.

Montreal, July 1st, 1913.

The market for pig iron in Canada is considerably disturbed by the action of both the American and English Market. Iron is now selling in Buffalo at $14.00 or the equivalent of about $18 20 laid down in Toronto. The result of this is that Canadian furnaces cannot continue to manufacture and meet prices at a profit, so it is claimed. As an evidence of this might be mentioned the fact that the Canada Iron Corporation is blowing out its big Midland furnace. This furnace has a capacity of 300 tons per day. The company will not cease to produce iron altogether, but will simply blow out the big furnace and keep the smaller one operating. The latter has a capacity of about 150 tons a day, and in order to fill contracts taken some time ago the company will require to keep this furnace operating.

Quite a little purchasing has been done of late by various interests which require iron, it being considered that it is very unlikely that prices will go much lower. In the United States, for instance, at least 20 blast furnaces have been blown out owing to the inability of the producers to meet prices at a profit. The situation is that several of the larger concerns own their own mines and their own boats and are in every way in a position to produce iron at a minimum cost, the result being, now that business is difficult to obtain, they are in a position to cut prices to a figure which cannot be met by a large number of their competitors. It is generally considered that this situation will mean that prices are now about the bottom, and this will have the effect of decreasing the production.

There has been a very severe break in prices of Iron in Great Britain. A few weeks ago, Middlesborough warrants were selling at 70s. 6d. This high price, no doubt was in the main due to a corner. In any case, during the past three or four weeks the price has broken and quotations are now 54s. 3d. At these prices it seems quite likely that a considerably larger import of English iron will take place. 10,000 tons is reaching port this week to fill orders taken from customers who require English iron for mixing purposes.

Prices hold very steady, being again unchanged, as follows:—

Antimony.—The market is firm at 10¼.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅛ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Building Paper.—Tar paper, 7, 10, or 16 ounces, $2 per 100 pounds; carpet felt, $2.50 per 100 pounds; tar sheathing, 43c. per roll of 400 square feet; dry sheathing, 35c. per roll of 400 square feet; tarred fibre, 62c. per roll; dry fibre, 50c. (See Roofing; also Tar and Pitch).

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is unchanged, being now per 100 lbs., as follows:—¼-in., $5.30; 5-16-in., $4.70; ⅜-in., $3.90; 7-16-in., $3.65; ½-in., $3.55; 9-16-in., $3.45; ⅝-in., $3.40; ¾-in., $3.35; ⅞-in., $3.35; 1-in., $3.35.

Coal and Coke.—Anthracite, egg, $8.50; chestnut and stove, $8.50 per ton, net; furnace coal, $8.25, net. Bituminous or soft coal; Run of mine, Nova Scotia coal, carload lots, basis, Montreal, $3.85 to $4 per ton; cannel coal, $9 per ton; coke, single ton, $5; large lots, special rates, approximately $4 f.o.b. cars, Montreal.

Copper.—Prices are 16¾c. Excellent demand.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c, and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are: Queen's Head, $4.35; Colborne Crown, $4.25; Apollo, 10¾ oz., $4.25. Add 25c. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lead.—Prices are firm at $5.35.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Nails.—Demand for nails is active and prices are: $2.50 per keg for cut, and, $2.45 for wire, base prices. Wire roofing nails, 5c. lb.

Paints.—Roof, barn and fence paint, $1 to $1.25 per gallon; girder, bridge, and structural paint for steel or iron—shop or field—$1.45 to $1.55 per gallon, in barrels.

Pipe.—Cast Iron.—The market is active and strong:—$36 for 6 and 8-inch pipe and larger; $37 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 73⅗ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73⅗ per cent. for black and 63⅗ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, July 2nd, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Antimony.—Unchanged at $10.25 per 100 lbs., very firm.

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Building Paper.—Plain, 35c. per roll; tarred, 43c.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton. Schaw station, and a good deal moving. Broken granite is selling at $1 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

MANITOBA GYPSUM CO. Limited
WINNIPEG - MANITOBA

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Coal.—Prices are quoted for this week as follows:—Youghiogheny lump, $3.85; river, $3.68; slack, $2.94; Solvey coke, $6.50; Connelsville coke, $5.45. Egg, stove and nut coke, $5.25. Pea, $6.75. Good market at these prices.

Copper Ingot.—The market is higher at 16 to 16½c., sheet copper case (16 oz. soft), 23½ to 25½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cent.

Felt Roofing.—Fairly active at $2.10 per 100 lbs.

Fire Bricks.—English and Scotch, $30 to $35; American, $25 to $26 per 1,000. Fire clay, American, $8; scotch, $12. Market steady.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Lime.—Retail price in city 30c. per 100 lbs, f.o.b. car; in large lots at kilns outside city 25c. per 100 lbs. f.o.b. car without freight. Hydrated lime $10 per ton at warehouse; delivered, $10.60; 30c. per single bag at warehouse.

Lumber.—An active movement is going on ,of both timber and lumber, prices much the same as before. Pine is good value at $32 to $40 per M. for dressing, according to width required; common stock boards, $28 to $33; cull stocks, $22; cull sidings, $20. Southern pine dimension timber from $32 to $45, according to size and grade; finished Southern pine, according to thickness and width $34 to $48; spruce hemlock is in demand and held quite firmly, we quote $22 to $26; spruce flooring in car lots, $25 to $29; shingles, British Columbia, are steady, we quote $3.75; lath, No. 1, $4.60; white pine, 48-inch, No. 2, have gone up and are now held at $4.25; for 32-inch, $2.75 is asked.

Nails.—Wire, $2.30; cut, $2.70, spikes, $3.00 per keg of 100 lbs., base.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Putty.—In bladders, strictly pure, per 100 lbs., $2.60; in barrel lots, plaster is being used. Plasterer's, $2.15 per barrel of three bushels, at warehouse.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.50 per barrel.

Plaster of Paris.—Calcined, New Brunswick, hammer brand, retail price, $3 per barrel, and but small stocks on hand at warehouse. New York hydrated lime $10 per ton at warehouse.

Ready Roofing.—Prices are as per catalogue.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Rope.—Sisal, 9½c. per lb.; pure manilla, 10¼c. per lb., base.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	0-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—23c. per lb

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.20; 22-24, $3.35; 26, $3.50; 28, $3.95; 29, $4.25; 10¾, $4.25 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 50 to 52c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Wheelbarrows.—Navvy, steel wheel, Jewel pattern, knocked down, $21.60 per dozen; set up, $22.60; Pan Canadian navvy, steel tray, steel wheel, $3.30 each; Pan American, steel tray, steel wheel, $4.25 each.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6.60 to $8 per cwt.

CAMP SUPPLIES

Evaporated Apples.—6c. per lb.

Butter.—Dairy prints are 23 to 25c. per lb.; creamery prints, 27 to 28c. per lb.

Canned Goods.—Peas, $1.35 to $1.75; tomatoes, 3s, $1.40 to $1.50; pumpkins, 3s, 85c.; corn, 97½c.; peaches, 2s, $1.50; strawberries, 2s, heavy syrup $2.40; raspberries 2s $2.15 with a tendency for lower prices on canned fruits.

Cheese.—New, large, 13¾ to 14c.; twins, 14¼c.

Coffee.—Rio, Green, 16c.; Mocha, 23 to 25c.; Java, 25 to 31c.; Santos, 17 to 18c.

Dried Fruits.—Raisins, Valencia, 8c.; seeded, 1-lb. packets, fancy, 8c.; Sultanas, choice, 10c.; fancy, 12c.; Filitras currants, cleaned, 7½ to 8c.; Vostizzas, 7½ to 10c.; uncleaned currants, 7 to 7½c.

Eggs.—New laid, 21 to 23c.

Flour.—Prices are maintained; thus, Manitoba flour, first patents, $5.40; second, $4.90; strong bakers', $4.70; Ontario flour, winter wheat patents, higher, at $4 to $4.25.

Feed.—Bran, $25 per ton; shorts, $27 per ton, scarce.

Lard.—Tierces, we quote 14½c.; tubs, 14¾ to 15¼c.; pails, 14¾ to 15¼c., tendency for higher prices.

Molasses.—Barbadoes, barrels, 35 to 50c.; West Indian, 27 to 30c.; New Orleans, 30 to 33c. for medium.

Pork.—Not much doing, short cut, $27 to $28 per barrel; mess, heavy, $22 to $23.

Rice.—B. grade, $3.33 per 100 lbs.; Patna, 6½ to 7c.; Japan, 6 to 7½c.

Salmon.—As before stated. We quote Fraser River, talls, $2.50; flats, $2.50; River Inlet, $2.35; cohoes, $2.20.

Smoked and Dried Salt Meats.—Long clear bacon, 15¾ to 16c. per lb. tuns and cases; hams, large, 18 to 18½c.; small, 20c.; rolls, 15½ to 16c.; breakfast bacon, 19 to 21c.; backs (plain), 23c.; backs (peameal), 24c.; shoulder hams, 12c.; green meats out of pickle, 1c. less than smoked.

Spices.—Allspice, 18 to 19c.; nutmeg, 30 to 50c.; cream tartar, 28 to 30c.; compound, 18 to 20c.; pepper, black, pure, Singapore, 19 to 20c.; pepper, white, 28 to 30c.

Sugar.—Granulated, $4.40 per 100 lbs. in bags; $4.45 in barrels, Acadia, $4.35; yellow, $4.30 per 100 in bags.

Syrup.—Corn syrup, special bright 3¾c. per lb.

Teas.—Japans, 22 to 35c. per lb.; Young Hysons, 16 to 35c.; Ceylons, 17 to 45c. per lb.

Vegetables.—Canadian potatoes, 75 to 80c.; Delawares, 85c. to 95c.; Egyptian, $2.75 bag; cabbages, 50c. dozen; apples, Winter, $2 to $3.25; turnips, 45c. bag; carrots, 65c.; parsnips, 75c. bag; beets, 75c. bag.

Winnipeg, July 1st, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c.; anvil and vise combined, each $5.50.

Axes.—Chopping axes, per doren, $6 to $10.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Building Paper.—Sheath, $1.10 per roll. Tarred felt, 8, 10 and 16 os., $2.35 per 100 pounds. No. 1 tarred, 88c. per roll; plain, 72c.

Copper Wire.—Coppered market wire, No. 7, $4 per 100 lbs., No. 6, $4; No. 10, $4.05; No. 12, $4.20; No. 14, $4.40; No. 16, $4.70.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Hinges.—Heavy T and strap, per 100 lbs., $6 to $7.50; light, do., 65 per cent.; screw hook and hinge, 6 to 10 inches, 5¼c. per lb.; 12 inches up, per lb., 4¼c.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Lumber.—No. 1 pine, spruce, tamarac, 2 x 4, 2 x 6, 2 x 8, 8 to 16 feet, except 10 feet, $29; British Columbia fir and cedar, 2 x 4, 2 x 6, and 2 x 8, 12 to 16 feet, $32; 2 x 20, 4 x 20, up to 32 feet, $42.

Nails.—f.o.b. Fort William, $2.50; Winnipeg, $2.90; cut, f.o.b., Winnipeg, $3.35.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7 60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Roofing Paper.—60 to 67½c. per roll.

Shingles.—No. 1 British Columbia cedar, $4; No. 2, $3.50; No. 1, dimension, $5; No. 1, band saw, $6.

Spikes.—Basis as follows:—¼, 5 and 6, $4.25; 5-15 x and 5-16, $4; ⅜ x 6, 7 and 8, $3.80; ½ x 8, 9, 10, and 12, $3.65; ⅝, $3.55; ¾, $3.50.

Steel Plates, Rolled.—3-16-in., $3.25 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Staples.—Fence, $2.50.

Timber.—Rough, 8 x 2, to 14 x 16 up to 32 feet, $38; 6 x 20, 8 x 20, up to 32 feet, $42.

Tool Steel.—8½ to 15c. per pound

The Canadian Engineer

An Engineering Weekly

THE COST OF GENERATING POWER WITH DIESEL OIL ENGINES

STATISTICS FROM PLANTS AT SHERMAN AND CLEBURNE, OPERATED BY THE TEXAS POWER AND LIGHT CO.—ACCEPTANCE TEST AND OPERATING COSTS.

By GORDON KRIBS,
Assistant Chief Engineer, Texas Power and Light Co.

THE Diesel oil engine was invented by Dr. Rudolf Diesel, the first working engine being produced in 1897. Since that time they have been gradually perfected until they have become a most reliable and efficient source of power. The demand for them has increased to such an extent that a large number of firms, including some of the largest and most reliable, both in America and abroad, are beginning their manufacture.

Up to the present time a considerable amount of information has been published relative to their operation and test, but accurate information as to the results to be accomplished by the use of Diesel engines over extended periods and under the varying conditions of actual practice, is mainly wanting. The Texas Power and Light Company are at present operating two Diesel oil engine plants, one at Sherman and the other at Cleburne, and it is the purpose of this article to set forth the actual operating results obtained under every-day operating conditions.

The Sherman plant consists of three 225-h.p., 3-cylinder, 4-stroke cycle engines, manufactured by the Busch-Sulzer Bros., Diesel Engine Company, of St. Louis, Mo., each engine being direct-connected to a 150-

Sherman Gas and Electric Company's 3—16—24 Diesel Engine No. 138.

Average air pressure - - - - - 70 atmospheres

(Oil consumption as shown averages 9.41 Gals. per 100 K.W. hours=6.46 Gals. per 100 B.H.P. hours.)

kw., 230-volt D.C. generator. These engines were installed January 1, 1905. They weigh about 100,000 lbs. and cost approximately $14,000 each.

The official acceptance test is given in the table shown on preceding page.

The oil consumption during the test averages 9.41 gallons per 100 kw. hours, which, with oil at 25 cents per gallon, is equivalent to 2.35 cents per kw.h.

During the year of 1910, 862,050 kw. hours were generated at a total fuel cost of $2,695.98, the fuel being the ordinary distillate as obtained from Texas crude oil, and costing $1.30 per barrel of 42 gallons, delivered. This oil has the following approximate characteristics:

Gravity, 37. Flash, 160. Fire, 190.

The operating expenses for the year were as follows:

Power plant wages	$3,014.00
Fuel for power	2,695.98
Water for cooling	37.07
Lubricants and waste	526.38
Miscellaneous supplies	63.78
Engine maintenance	411.12
Total	$6,748.33

Thus, for the year 1910, the cost per kw.h. for fuel was 3.1 mills, and the total cost per kw.h. was 7.1 mills. This, while not including interest on the investment, depreciation, or other so-called overhead expenses, is cer-

tainly exceptionally low in cost per kw.h. for a plant of this size.

In the accompanying Table II. are given the results for the 12 months' period from March, 1912, to February, 1913. It will be noted that the total cost of production per kw.h. was 6.78 mills with fuel oil at $1.05 per barrel of 42 gallons.

The plant at Cleburne consists of three 225-h.p. units similar to those at Sherman, with the exception that each engine is direct connected to a three-phase, 2,300-volt, 60-cycle alternating current generator. It is worthy of note that no trouble whatever has been experienced in paralleling these machines.

In the accompanying Table III. we give the results of 12 months' operation at this plant.

In conclusion, the writer wishes to state that for small and medium sized plants, he believes the Diesel oil engine to be the most efficient prime mover available, and while the engine is now built only in comparatively small sized units, there is no doubt in the future it will be developed in large sizes and made available where a large quantity of power is desired. The first cost of the engine is high, and in some cases this may be a drawback.

It is also essential to have a good mechanic as head plant engineer, as the engine requires intelligent handling. They are, however, far from being the trouble-makers internal combustion engines are supposed to be, and are giving excellent service in both of the plants above mentioned.

SUITABLE ROAD SURFACES FOR VARIOUS KINDS OF TRAFFIC.

THE study of the effect of different kinds of traffic on roads and of the most suitable surfaces to withstand them, as carried on by the Massachusetts Highway Commission, was the subject of a paper entitled "Traffic Census of Roads in Massachusetts," by Mr. William B. Sohier, chairman of the commission, and presented at the convention of the American Road Builders' Association last December. The commission has come to the popular conclusion that roads used by large numbers of swiftly moving vehicles require special attention to prevent disintegration and rutting, and that such traffic cannot be carried on successfully over gravel or water-bound macadam roads unless amply protected. The results of the investigation in Massachusetts show that the use of some dust layer or binder is an absolute necessity. Where a road is subjected to traffic varying from light, swiftly moving vehicles to heavily laden trucks, the adoption of a surface to prevent excessive wear is arrived at by re-surfacing with some form of bituminous mixture to a depth of several inches of the road.

Motor-Vehicle Traffic.—Some oiled gravel roads are satisfactory and very economical, if they are constantly and properly maintained, even where there are large numbers of swiftly moving automobiles a day, at least, in the summer months, but where there are not many heavily loaded wagons. Some of these roads have 500 automobiles or more a day, and yet they are cheaply built and cheaply maintained. Roads built of sand and asphaltic oil also stand up well under heavy motor-vehicle traffic, but these roads have very little heavy teaming on them. Heavy wagons and many heavy motor trucks rut such roads quickly and soon wear them out.

Maintenance Costs.—When the motor vehicle appeared in fair numbers upon the roads Massachusetts had 600 to 700 miles of state highways (now over 900), and they were mostly water-bound macadam, with some few miles of gravel road.

These highways had been built from 1 to 14 years previously, very few miles had been resurfaced, and the Highway Commission had only $100 a mile a year to spend for maintenance and resurfacing, and not that much except for the last few years. The maintenance of these old roads was our problem in 1908, and has been ever since.

Automobile travel has increased 40% and the total traffic 14% a year, and these roads must be maintained, or the state's money, borrowed on long-time bonds, would be lost and wasted; the good roads would be gone, but the bonds would still remain to be paid.

The state doubled its appropriation for maintenance in 1908, giving the Highway Commission $200,000 a year instead of $100,000. The motor-vehicle fee was also increased, and the right to use the net fees for the maintenance of roads was obtained. These two sources of revenue for the last three years have provided about $500,000 a year, for maintenance; an average of $450 a mile a year, and we are at least holding our own.

Bituminous Binders and Dust Layers for Old Roads.—Many miles of old roads have been saved by spreading a coat of asphaltic oil, light or heavy, or tar over them. To-day some asphaltic binder or dust layer has been used on over 80% of our state highways. The only roads on which it has not been used are those located in the country districts where there is very light traffic.

During the year 1912 we used nearly 2,000,000 gal. of bituminous material in construction or maintenance. Over 800 of the 930 miles of our state highways received some form of bituminous treatment. We have resurfaced as many miles of road every year as we could; using, where the traffic was heavy, a bituminous macadam on the top 3 in.

Effect of Traffic on Bituminous Surfaces.—Massachusetts has four division engineers, on its highway work. They were asked the same questions relating to different tars, oils, asphalts, etc., and for their opinions of the relative merits or demerits of each.

The answers were all different. One had used tar on the surface successfully, another had not. One liked tar for penetration or mixing; another preferred an asphaltic compound. The same was true of the use of various asphaltic oils as a blanket coat, or as a dust-layer. One preferred a heavy cold oil, another a heavier hot oil. There was, however, if the traffic and other conditions in each case were carefully studied, a real agreement in all essentials.

Where Heavy Oils Fail.—We have a good many miles of old macadam road which have been saved and maintained by ½ gal. of hot asphaltic oil spread upon each square yard of surface and properly covered with sand and pea stone or gravel. Many of these roads have worn three years, and in their fourth year are still in good condition. A few miles have worn four years and are now on their fifth year. The patching has cost but little, from 1 to 3c. per sq. yd. a year.

These roads often have very heavy automobile travel, possibly over 1,000 cars a day. They often have large numbers of teams daily. One has over 500 teams and 1,000 automobiles, and a heavy blanket oil surface has worn reasonably well for three years, and will for a fourth

year except in a few places. This same road also has an average of 55 motor trucks a day.

Near two traffic taking stations, where the teaming was heavy, for one-quarter of a mile in each place (out of four miles), the blanket oil failed. It crumbled, went into mud, developed holes and was disappearing. We have replaced the top 3 in. with an asphaltic bituminous macadam.

Heavy Horse-Drawn Wagons Cause Failure.—The traffic study shows that it is not the number of wagons, but heavy wagons—two or more horses and heavy loads on narrow tires—that cause the failure. The failure of roads treated with heavy oil has occurred on a few miles of road at certain places where it was clear that heavy horse-drawn wagons were responsible.

In two instances it was 50 to 75 ice-wagons a day, together with other wagons, carrying 3 tons or more each on 2½ to 3-in. tires which did the damage. In a month the oil surface began to crumble and break up on the side of the road on which the loaded teams travelled. The surface lasted three months on the other side of the road where these wagons came back empty. The same road, treated with the same oil, is still in good condition beyond the ice-houses. In one case for 3 miles, in the other for 15 or 16 miles, the oil surface is three years old and still needs only patching. Light cold oil has been substituted as a dust-layer and has proved reasonably satisfactory, though the stone of course is wearing out, and a bituminous macadam would probably prove economical.

In 1909 another important road, which had been covered with a hot oil blanket, was rutting and wearing out rapidly. A coal team was passing to some hotels three or four times a day during the summer (carrying 6 or 7 tons of coal on narrow tires). When a motor truck was substituted for the coal team the surface of the road, which had been oiled, was again in good condition. It has worn three years and now needs only patching.

Hot Oil Blanket Surface.—A hot oil blanket surface, made of a good asphaltic oil, will be economical and will carry large numbers of automobiles at high speeds (over 1,000 a day in summer) for several years, will carry large numbers of light wagons (500 a day), and quite a number of motor trucks (50 or so a day), but will be destroyed by a large number of heavy wagons, especially those with narrow tires. Fifty or more such vehicles daily, farm wagons, wood wagons, etc., will rapidly destroy the road surface. A surface coat of a good quality of tar will last satisfactorily under a large amount of automobile travel, but usually it has to be renewed more often than a good quality of oil.

In all cases it is assumed that holes and depressions will be filled before tar or oil is used, that the bituminous material is evenly distributed and is sufficiently covered and kept so that it will not be picked up on tires, and that all holes that develop are patched at once as soon as they appear.

Constant repairs, at a cost of 1 to 2c. a sq. yd. a year will save an expenditure of from 40c. to $1 a sq. yd. for the resurfacing of these bituminous surfaces if they are allowed to go to pieces; and they will do it in a year or two at the most, if not cared for properly.

When these surface treatments fail, as they will where the traffic is extremely heavy (heavy in weight of vehicles, not numbers of vehicles), then some more permanent form of construction must be selected and the road reconstructed as soon as possible. It will prove to be true economy in the end, and the end is not far off.

Light cold oils, water-gas tar, etc., used as dust-layers help to prevent the ravelling of roads. These materials may be economical and work satisfactorily for small wagon traffic (30 to 50 a day) and medium automobile traffic (50 to 100 a day), provided the road is not one where high speeds are usual.

They may also help to preserve the road from the effect of automobile traffic where the team traffic is too heavy, or the loads are carried on such narrow tires that a hot oil blanket surface will not wear satisfactorily, until money becomes available to resurface the top 3 in. with some form of bituminous macadam.

Conclusions Summarized.—The accompanying table shows as nearly as possible the results observed after four years of experience with bituminous materials, comparing these results with the traffic going over the road in 1909 and again in 1912.

It is fully realized that more experience will undoubtedly cause changes or modifications in some of the present opinions.

Table Showing Kinds of Road Surfacing Best Adapted to Different Classes of Traffic for a Standard Road 15 Ft. in Width, With a 3-Ft. Gravel Shoulder on Each Side.

	Average Daily Traffic			
	Light wagons	Heavy wagons one horse	Heavy wagons 2 or more horses	Automobiles a day
A GOOD GRAVEL ROAD will wear reasonably well and be economical with	50 to 75	25 to 30	10 to 12	100 to 150
Needs to be oiled with				over 150
OILED GRAVEL fairly good either hot or heavy cold oil ½ gal. coating (cold oil must be used yearly)	75 to 100	30 to 50	20	500 to 700
WATER-BOUND MACADAM will stand with	100 to 150	175 to 200	60 to 80 perhaps more	Not over 75 at high speed
Dust-layer will prove serviceable on such macadam with				50 to 100
Macadam will then stand (but the stone wears, of course), with				300 to 500
WATER-BOUND MACADAM WITH HOT OIL BLANKET COAT will be economical with	250 to 300	75 to 100	25 to 30	Up to 1400 and more with fewer teams
Will stand at least	50 motor trucks		probably more	
But will crumble and perhaps fail with over		100 on narrow tires	50	
	(loaded farm wagons, ice and wood wagons, etc.)			
WATER-BOUND MACADAM WITH A GOOD SURFACE COATING OF TAR will stand with	30 to 50	25 to 30	10 to 15	1800

The quality of gravel or other material and the speed of motor vehicles in particular localities are important factors and account for the above minimum and maximum variations.

It has not yet been satisfactorily determined when the weight of traffic makes it more economical to use a bituminous macadam, either tar or asphaltic products by penetration with a sealing coat of tar or asphalt, or by the mixing method, but it is believed that some such method would be economical and desirable where the team traffic is so heavy (75 to 100 heavy wagons on narrow tires with two or more horses), that a heavy, hot oil blanket surface will not carry the traffic but fails within the year.

We have several such bituminous macadam roads which have stood for three or four years very well indeed, but time alone will determine the ultimate economy. In surfacing with a 3-in. bituminous macadam top the extra cost for such top has varied from 30 to 60c. a sq. yd., depending on material and methods used.

ARTIFICIAL ICE MANUFACTURE IN OTTAWA.

By Gerald L. Kirwan, B.A.Sc.
Topographical Surveys Branch, Department of the Interior, Ottawa.

THE provision of pure water and pure ice is a problem that has reached an acute stage in municipal affairs, and the satisfactory solution of it, at a popular price, will be heartily welcomed in numerous Canadian municipalities. Ottawa, Ontario, is trying out a system that promises to give the maximum of satisfaction, in so far as the purity of products and their price is concerned. The company (The Artificial Ice Company of Ottawa) has strong co-operation and support, and claim that they are in a position to meet any competitive selling price on the part of natural ice dealers, and still produce a much superior product. They have just started the production of about 5,000 gallons of double-distilled, re-oxidized water, in addition to the demands of their daily ice market. The plant is designed to turn out fifty tons of ice per day with provision for 75 to 80 tons in emergency weather. About 15 men comprise the working staff. Mr. P. D. Lyons, as manager, and Mr. R. W. James, mechanical engineer, had charge of the construction of the plant.

Briefly, the system may be outlined as follows:—

Evaporation.—City water is taken from the hydrant, and evaporated to steam in a boiler 54 ft. long by 6 ft. in diameter. The company (The Artificial Ice Company of Ottawa) owns, however, two wells, each sunk on their own property to a depth of 360 feet, forty feet of which are through clay, and the remainder through solid limestone—a formation that obtains largely under Ottawa. Hence, the water is a reasonably pure product at the beginning of the process. A small air compressor will be used to pump the water from the wells to the boiler, the pipe lines of which are being laid with all possible caution against the introduction of scale from the pipe itself, or of foreign materials from any source.

Condensation.—The steam from evaporation is introduced at 110 pounds working pressure into the first of eight Reilly multicoil evaporators—boilers about 7 ft. high by 2 to 3 ft. in diameter, and each one containing a vertical coil of pipe. Passing through this pipe-way from top to bottom, and thence to the next boiler, the steam condenses, each boiler providing steam at lower pressure for the next until finally the pressure has dropped to a 28-inch vacuum. This vacuum serves the beneficial purpose of removing most of the contained air from the condensed steam, air, in the finished product giving the ice a snowy, cloudy appearance which, in the popular mind, robs it of the purity associated with crystal ice. It also causes the ice to melt and check much more readily than the properly finished product.

As the condensed water from the boilers concentrates in a pump nearby it opens a steam valve on assuming at a certain head (about 12 inches). The pump, thus automatically opened or shut, accordingly as the head of water rises above or falls below the height required, pumps the doubly distilled water through a system of pipes automatically cooled by contact pipes containing running city water at about 55 or 60 degrees F.

Filtration.—The cooled, distilled product is pumped from bottom to top through four strongly riveted galvanized-iron boilers. Inside the true bottom of each, and a few inches above it, is a perforated false bottom. The space between each perforated pair of bottoms and tops is filled with finely divided, well-washed, hard maple charcoal, the function of which is to catch any possible sediment in the water that might get through from the distilling part of the process, (although the pipes and valves have been specially made and assembled with caution against such an occurrence). Each boiler is about 6 ft. high and 3 ft. in diameter, and the four will easily handle all the water the plant has capacity for, on account of the freedom from sediment of the distilled product.

Leaving the boilers, the water is pumped to a 3-ton storage tank, about 20 feet above the level of the floor. Here it is pre-cooled to about 35 degrees F., in order, by condensing its volume, to drive out the last remnant of air. It is now ready to be turned into ice in the "freezer"—the portion of the process which deserves special and continual attention, as it is the important phase of the operation. The details, however, have been so well attended to that it is doubtful if a shut-down of any considerable importance would ever be involved.

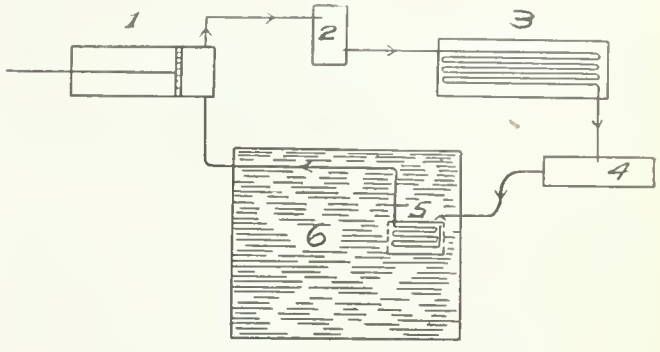

Fig. 1.—Details of Freezing System.
(1) Compressor; (2) de-oiler; (3) water-coolers; (4) condenser; (5) "shell" cooler; (6) "brine" tank.

The "Shell" Freezer.—In one compartment of the building is a tank 65 ft. long, 30 ft. wide, and standing 5 feet above the level of the machinery floor. Its floor and walls are of concrete, and its roof is a wooden structure possessing small trap-doors, each opening being about 2 feet by 1 foot—large enough to admit a can containing water from the storage tank to be frozen in the "brine" solution below this floor level. "Brine" is, properly speaking, a misnomer, as instead of common salt, calcium chloride, which has a more effective freezing action, is used, in the proportion of about 20 pounds to a cubic foot of water. The solution, kept in circulation by an electrically driven paddle, comes in proximity to ammonia in a cooling tank for the purpose of extracting its heat. This cooler is a boiler 15 feet long, 44 inches in diameter, and is situated in one end of the freezing brine tank, being equipped with an interior end-to-end series of pipes, very much like an ordinary steam boiler. Through these pipes ammonia flows, and they are surrounded by the brine solution in much the same manner as a furnace flame sweeps in and around the boiler-pipes. The purpose of the ammonia, as stated, is to extract heat from the brine, to reduce the temperature of the latter sufficiently low to freeze the distilled water in large cans placed in it.

To produce this freezing action, the following explanation and compression cycle is utilized: Gaseous ammonia, compressed to 150 pounds, ultimate working pressure, is discharged into an oil-settling tank, from which it flows through a condensing system of water-cooled

pipes into a gathering tank. From here it passes through an expansion valve directly into the "shell" cooler, where it suddenly expands until its pressure drops from 150 to 15 pounds per sq. in. It proceeds at once in this state to draw heat from the surrounding brine in order to make up as much heat per unit volume of ammonia as it had before. Thus its temperature of vaporization is again attained, and in passing from the liquid to the gaseous state its excessive heat of vaporization is derived from the "brine," as it passes through the "shell" cooler and back again, to the compressor as a vapor. The ultimate result is that in the compressor the ammonia temperature may be well over 100 degrees F. and that of the "brine" in the tank approximately zero. Eight above zero is a good working temperature. Eight below, while producing ice much more rapidly than eight above, checks it, however, making it more brittle and cloudy. If, by any chance the "brine" reaches eight below, the compressor is generally stopped long enough to enable the system to rise fifteen degrees or so.

As the ammonia returns to the compressor, the cycle is repeated and, being continuous, the fresh ammonia running through the "shell" cooler, does its work much more quickly than would be possible with an intermittent cycle. The pipes themselves are good indicators, (i.e., those in connection with the freezing system), since they

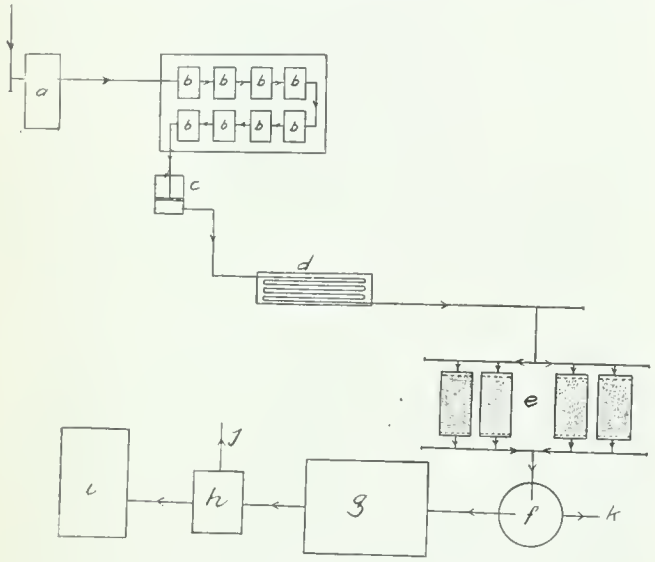

Fig. 2.—Flow-Sheet of System.

Well-water to: (a) Evaporating boiler; (b) 8 Reilly multicoil condensers; (c) automatic steam-pump; (d) water-coolers; (e) 4 mechanical filters; (f) 3-ton storage tank; (g) freezing system; (h) distributing room for ice; (i) store-room; (j) to city delivery; (k) pure water supply.

show frost on the outside at the level of the frozen ammonia liquor in the "shell" cooler, and of "brine" in the tank. It may be remarked in passing that the loss in ammonia is exceedingly small, very little replenishing being necessary in years.

The advantages claimed for this freezing system over the old systems are as follows: It costs, for a 50-ton-a-day plant, $1,000 less, saved chiefly in pipe installation. Also, the wear and tear is very small compared with the old system—as, for instance, the cans containing the freezing water lie in "brine" solution, without having to be jammed down among these old-fashioned coils of piping. It is also claimed that 33% more production is obtained, That advantages like these cannot be overlooked is obvious.

The actual freezing is carried out as follows: The water is led from the storage tank through rubber piping to the freezing-cans. These are 510 in number, and are each 8 ft. by 4 ft. by 1 ft. They are made of riveted galvanized iron, and are guaranteed for four years. When full, a can weighs 400 pounds. A patented automatic nozzle is attached to the feed-hose, and the operation of filling is as follows: The workman opens the feed valve, the water pours into the can; as the level rises, it pushes up a hood on the nozzle till, at a certain height, this hood catches a spring, releasing it, and closing the feed-valve. A can takes about 36 hours to freeze, and as fast as one is removed full of ice, a water-filled can takes its place in the brine. The ice-can is lowered into warm water a minute to loosen up the block of ice inside; then raised by compressed air and tilted on a shaft, opened, and the cake of crystal ice slid along a trough to a drained concrete chamber for cartage to customers, or for storing in a 350-ton store-room.

UTILIZING WOOD WASTE.

Perhaps the most interesting development in the manufacture of wood products has arisen in the increasing variety of uses to which wood-waste can be put. Beginning in the forest the closer utilization of the various wood-products can be traced through the saw-mills and large wood-working industries, right down to the firms working only on small specialized lines.

It is now commercially possible to reduce the fifty to sixty per cent. waste formerly left in the woods by the lumberman to no more than five per cent., by a combination of three well-developed chemical industries, namely, paper-making, wood-distillation (in a modified form) and the manufacture of resin oils. Practically all the valuable constituents from the stump, tops, branches and defective stems which would otherwise be left to rot in the forest are thus converted into useful commodities.

The utilization of mill waste is being made increasingly possible by the developing markets for odd and short lengths in lumber instead of a few assorted sizes. Many saw-mills use their waste products in the manufacture of laths, mouldings, pickets, roller-blinds and paving blocks. The manufacture of wood-pulp from the small waste-wood now being fed to the burner is also a commercial possibility. Even sawdust has its uses, and in countries where more intensive utilization prevails it is being successfully manufactured into a variety of products. Several plants have been erected in this country for its manufacture into ethyl (or grain) alcohol, sugar and briquets for fuel.

The bulletin now being issued by the Forestry Branch, Ottawa, on "The Wood-Using Industries of Ontario," throws considerable light on the utilization of wood-waste. Sash and door factories sell or use their short ends and trimmings for the manufacture of boxes, baskets, bobbins, butter-moulds, insulator pins, novelties, skewers, spindles, spools, stakes and woodenware. They bale their common sawdust and sell it for covering for the manufacture of composition novelties, and for cleaning screws. They sell shavings for bedding, packing and for drying wet land. Hickory and other hardwood dust is sold for smoking meats. In fact, wood manufacturers will soon be able to boast of using all the wood but the bark—and even that, in the case of some woods, such as hemlock, is of considerable value.

THE GENERATION OF ELECTRICAL ENERGY FOR SMALLER TOWNS

DATA CONCERNING CONSUMPTION OF LIGHT AND POWER — PLANT DUPLICATION FOR RELIABILITY OF SERVICE — FEATURES GOVERNING PLANT DESIGN AND EQUIPMENT.

By M. M. INGLIS,
Electrical Engineer, Yorkton, Saskatchewan.

IN a paper read at the eighth annual convention of the Union of Saskatchewan Municipalities, and entitled "The Generation and Distribution of Electrical Energy for Light and Power Purposes in Medium and Small Sized Towns," Mr. Inglis began by citing a few statistics covering a number of towns having generating units installed, and the degree of patronage extended to them, but his remarks were based largely upon the comparative suitability of the various types of prime movers, for small installations.

In towns of 1,000 to 1,500 population the average number of consumers is approximately fourteen per hundred.

In towns of 1,500 to 2,500 population the average number of consumers is approximately sixteen per hundred.

In towns of 2,500 to 3,000 population the average number of consumers is approximately thirteen per hundred.

The average consumption per capita in towns from 1,000 to 5,000 remains fairly constant, and from data collected that consumption is approximately 60 watts.

Thus in a town of 1,000 inhabitants the output required of the generating unit would be 60 kw., or taking the efficiency of the generator as being 90%, then the output of the prime mover would be approximately 90 b.h.p. Similarly with a population of 5,000 the output of the electrical equipment would require to be 300 kw., or with a generator efficiency of 92% the output of the prime mover would be approximately 440 b.h.p.

In order to maintain a thoroughly reliable service during the 24 hours of the day, it is absolutely necessary to duplicate the plant. Consequently, for a town of a thousand population the total generating capacity ought to consist of two units of 90 b.h.p. capacity. However, as most towns only run their plant during the lighting period, or approximately ten hours per day out of the twenty-four, on a yearly average, the question crops up as to whether it is necessary to install this duplicate unit. This question is usually decided by the financial position of the municipality and whether there is sufficient demand for power during the remaining fourteen hours of the day. In most cases only one unit is installed.

Salient Points Governing Installations.—The most important items to be considered in locating small central stations are:—

(1) The method of driving the generators.

(2) The proximity of fuel supply.

(3) Pure water supply.

(4) Railroad facilities and the possibilities of later expansion.

Although I have numbered these items, I have by no means attempted to place them in their order of importance, because they will each affect to a more or less degree the different type of plant which it is proposed to install. The first mentioned, namely, the method of driving the generators, from an engineering point of view, seems of primary importance. Considering the two types of drive universally used, namely, the belt drive and the direct connected drive, experience has shown that the belt-driven plants are less efficient and much less reliable than the direct connected unit. This is due principally to belt troubles. Much more floor space is also required for the belt-driven type of plant, consequently a larger building is required in which to house them. As important as any of these drawbacks is the inferior regulation which is very apparent when no automatic regulator is connected in the electrical circuit, especially if the load is at all variable. The only advantage the belt-driven type has over the direct connected type is a lower first cost, but this is hardly worth considering when compared with the advantages which accrue from the direct connected type.

The second item: The proximity of fuel supply. This is an item of considerable importance in these parts where freight rates are so high, and the municipality which has close at hand a good source of fuel supply is extremely fortunate, in so far as it will materially reduce the cost of production of energy. It will also be one of the deciding factors in arriving at the type of plant to be installed.

The third item, namely, pure water supply, will also be a deciding factor, as all the prime movers in use to-day use water to a more or less degree, either in the direct process of generation or as a cooling medium.

The last item, but none the less important, is that of railroad facilities and the possibility of later expansion. The railroad facilities we are all familiar with for the handling of the fuel supply, but the possibility of later expansion is one that cannot be given too much consideration, as not a few instances can be seen where inadequate provision has been made for future extensions. If the proper precautions were taken in deciding upon the best type of plant for each individual case, and provision made for future extensions, then a great deal of time and money would be saved as well as greater possibilities obtained of supplying energy at a lower rate in the future.

Taking the case of one unit being installed, and for instance, say, a 100 b.h.p. unit, this is equivalent to an electrical output of approximately 68 kw., taking the efficiency of the generator at 91%. Assuming the plant to run on an average ten hours per day during the period of one year or, say, three thousand hours, then the maximum number of units generated would be 204,000. This is only true if the plant is run on full load during the entire period. In actual experience, however, the total units generated approximate a yearly average 15% of the maximum, which is equal to 30,600 units. Assuming the cost of energy to be 15 cents per unit with no allowance for distribution loss, then the yearly revenue would be equal to $4,600. Knowing the principal and interest payable yearly on the debenture issue, as well as the fuel and operating expenses, with a liberal allowance for depreciation, it is an easy matter to determine whether or not the cost per unit, namely, 15 cents, is sufficient to

meet this expenditure. In this manner it is possible to figure out a rate at which the undertaking will be self-supporting. With small plants the biggest items of expenditure are usually the fuel bill and wages. In order to keep these to a minimum it is necessary that the most efficient and reliable plant be installed combined with simplicity in operation.

Steam, Gas and Oil Engines.—The steam engine in favor to-day for small central station work is the vertical compound high-speed engine, fitted with piston valve, automatic governor and having forced lubrication throughout. This type has proved itself very suitable in so far as reliability and speed regulation are concerned. The operation of the same is simplicity in itself. There are, however, other items to contend with in a steam installation just as important as the engine itself. One of these I have previously mentioned, namely, pure water supply. In connection with this, all are familiar with the difficulties attending an impure or shortage of supply. These call for proper and costly treatment on the one hand, and an unreliable service is the result on the other hand, attended with loss of revenue from the sale of energy. There are also injectors, pumps and boilers, which are often more troublesome than the actual prime mover itself. The whole of these difficulties may not be met with, but there is one difficulty attending all small steam installations and, to my mind, a very important one, that is *the stand-by losses*. These ought to be given due consideration when it is intended to install a generating plant. Take the case of a plant running only ten hours out of the twenty-four; for the other fourteen hours there is quite an appreciable loss for which there is absolutely no return, besides there is also the cost of labor looking after the boiler equipment during the non-working hours. Taking this loss of fuel, in addition to the actual fuel consumed during the generating period and with a load factor of 15 per cent., the consumption of coal will be approximately six to seven pounds per unit generated at the switch-board. Taking this lower consumption and coal at the price of $7 per ton, this is a generating cost of 2.1 cents per unit.

Of the gas engine plants the suction gas producer equipment seems to hold the field. These plants are proving themselves more and more reliable and are very suitable for small stations. They are, however, less reliable, although more economical than the steam engine. The greatest difficulty in connection with these plants is usually met with in the gas producers, and in spite of the statements to the contrary, it requires an experienced man to care for the producers, to obtain the best results and keep the plant in first-rate condition. The principal troubles are the keeping of the combustion zone within the proper limits, the removal of ashes and clinkers, and the effects of impurities in the gas. This first trouble is usually caused by the fuel not being kept consolidated during operation. The second due to improper regulation of steam which causes high combustion temperatures, if there is sufficient steam with consequent fusing of incombustible matter. When the ashes and clinker are being removed, and especially in the smaller sizes of producer, little or no provision is made to exclude the air from entering, thus causing an irregularity in the quality of the gas produced. This, you can understand, will naturally affect the running of the engine.

Let us consider the cycle of operation in the engine. During the first stroke, a mixture of air and gas is drawn into the cylinder. On the second stroke this mixture is compressed. At the end of the compression stroke the mixture is ignited by means of an electric spark from a magneto or some such apparatus, thus we have explosion and subsequent expansion during the third stroke. During the fourth or exhaust stroke the products of combustion are set free to the atmosphere. This completes the cycle of operation. The combustion of the gases is accompanied by the formation of a carbon deposit in the cylinder and it sometimes happens even though due precautions are taken, that this carbon, which is at a high temperature, is sufficient to prematurely ignite the fresh mixture during the next cycle of operation. This premature ignition sets up undue strains in the mechanical parts of the engine, which are liable to cause trouble. It is thus found necessary to withdraw the piston in this type of engine at approximate intervals of three months, in order that the carbon deposit does not interfere with the working of the engine. There are also the stand-by losses to be considered, but these are not of the same magnitude as with a steam equipment. In a suction gas plant of the same capacity as that quoted in connection with the steam plant, and under the same conditions, the consumption of coal would be approximately four pounds per kw. generated at the switch-board. Taking coal at $8 per ton, this would mean a cost of approximately 1.6 cents per unit.

In considering the oil-burning engines, I might just mention that it has been a recognized fact both theoretically and practically, that the higher the compression in the internal combustion engine the more efficient would it become. One reason for the keeping of this compression at a moderately low figure has been due to the excessive temperature caused by the compression and the likelihood of this high temperature igniting an explosive mixture such as is compressed in the ordinary gas engine. This difficulty, however, has been overcome in one type of internal combustion engine which is considered one of the foremost prime movers on the market to-day, that is the Diesel crude oil engine. The cycle of operation may be described as follows: During the first or suction stroke, air only is drawn into the cylinder. On the second stroke this air is compressed, and at the end of the compression stroke the fuel oil is sprayed in finely divided particles into the cylinder. The air temperature, being high, as the result of compression, the finely divided oil burns as it enters the cylinder. This spraying of oil is continued during a considerable portion of the outward stroke, and during the remainder of this the third stroke, the products of combustion and the surplus air expand. During the fourth or exhaust stroke the products of combustion are driven off to the atmosphere. This completes the cycle. It will thus be noticed that air only is compressed and not a mixture of air and combustible vapor or gas: consequently, whatever the pressure of compression and whatever the temperature, premature ignition cannot occur, there being no fuel to ignite. Therefore the greatest economical advantages of high compression can be utilized. There is, however, the disadvantages of high compression, which are all more or less of a mechanical nature, but these difficulties of a recent development are being largely eliminated. The Diesel engine, like all other prime movers, is not immune from trouble. It may be the sticking of a fuel valve, the hanging up of a compressor valve, or a leaky exhaust valve. All of these defects may be of little or no importance, and may cause a shut-down of only a few minutes, yet there is that interruption in the service which always means a loss of revenue. To my mind the only great disadvantage in connection with the Diesel oil engine is a possible short-

age of fuel supply. So far as I know there is no decrease in the actual production of oil, yet there is that ever-decreasing demand for the finer and crude oils. Up till the present there has been no difficulty in obtaining fuel oil, but the price has increased almost fifty per cent. during the past twenty months. It might also be interesting to know that the freight on fuel oil to Saskatchewan is approximately equal to the cost of oil in its home market. Under the same conditions as that of the steam and gas producer plants before mentioned, the oil consumption is approximately .12 of a gallon per unit generated at the switch-board. Taking the price of fuel oil at 12 cents per gallon, this gives a cost of 1.44 cents per unit.

Comparing the three types of prime movers discussed we have:—

Steam, with coal at $7 per ton, 2.1 cents per unit.

Gas, with coal at $8 per ton, 1.8 cents per unit.

Diesel, with oil at 12 cents per gallon, or approximately $27.60 per ton, 1.44 cents per unit.

In concluding the generating part of this paper, I might say that the labor costs are highest for gas engines and lowest for Diesel engines, with steam plant taking a position about midway between the two.

ENGLAND'S EXPORT TRADE.

According to the Board of Trade the following are the values of produce and manufactures exported by the United Kingdom to the leading countries and self-governing dominions:—

Germany	£40,362,767
Australia	34,840,701
United States	30,065,806
France	25,585,681
Canada	23,531,311
South Africa	21,420,912
Holland	14,281,668
Belgium	12,193,306
New Zealand	10,390,334

GRANITE AND TRAP-ROCK IN CANADA.

The production of granite and trap-rock in 1911, according to returns from forty-seven active firms reporting, and contained in the statistics given in the annual report on the mineral production in Canada, by John McLeish, B.A., was valued at $1,119,865, as compared with a production by thirty-three firms, valued at $739,516, in 1910; showing an increase of $380,349, or 51.4 per cent. There was a particularly large increase in the value of granite used for building purposes and in the production of crushed stone.

Quebec province was again the largest producer, the value of sales in 1911 being $462,678, as compared with $356,257 in 1910. The value of sales in British Columbia in 1911, however, approached very closely to that of Quebec, being $460,851, as against $244,767 in 1910. Ontario produced granite to the value of $131,816 in 1911, as compared with $109,678 in 1910. Both New Brunswick and Nova Scotia showed an increased production, the value of the New Brunswick output being $37,994. Much of the rough stone quarried in New Brunswick, as well as stone imported from Redbeach, Maine, and Mt. Johnston, Que., is worked up into finished monumental and ornamental stone at mills at St. George, the value of the finished product here in 1911 being $86,658.

BRIDGE FLOORS REPLACED WITH CONCRETE

MR. L. C. Smith, engineer for the Michigan State Highway Commission, in the fourth biennial report of the commissioners, advises the use of concrete wherever possible in the replacing of floors on old steel or wrought iron bridges, even though this may necessitate the laying of new steel stringers.

This plan has been followed for assumed load specifications and computing stress in truss:

(1) Concentrated wheel load of five tons on area 12 inches by 28 inches on floor slab.

(2) Concentrated wheel load plus weight of slab on two stringers spaced not more than 28 inches apart.

(3) Distributed ten-ton load plus dead floor load on floor beams.

(4) Ten-ton concentrated load tried on each panel joint plus dead load of whole bridge for the trusses.

In no case have concrete floors been recommended where the stress in the steel would be above 17,000 pounds, and in wrought iron above 13,000 pounds.

The following general specifications are used:

Steel.—Steel stringers shall be spaced not more than 28 inches nor less than 24 inches centres.

For panel lengths, from 12½ feet to 14 feet and width of roadway 16 to 18 feet. Eight-inch 18-pound I-beams shall be used for three centre stringers. On each side of these, two 7-inch, 15-pound I-beams, and, in place of side channels, 6-inch 12¼-pound I-beams shall be used at each edge. All stringers shall be long enough to reach two panel lengths, and be laid so as to break joints. Stringers shall be bolted to floor beams securely with one-half inch bolts at each intersection. Stringers shall be connected at ends with two three-eighths inch fish plates 14 inches long and wide enough to fit snugly between flanges. Fish plates shall be bolted with eight one-half inch bolts in each plate. Not more than one-quarter inch, nor less than one-eighth inch shall be allowed between ends of stringers.

All abutment and pier ends of stringers shall be bedded in Portland cement mortar mixed 1:3.

All floor beams, sway bracing stringers and connections shall be coated with two coats of linseed oil paint. Tops of stringers must not be painted.

Forms.—Forms shall be placed between stringers tight up under top flange. Tar or builders' paper must be used on forms to make them tight.

Curb forms shall be securely fastened in place before any concrete is placed.

Reinforcing.—Expanded metal No. 40—3-inch U.S. or Kahn rib metal No. 3 wire reinforcement, having the same area of cross-section per foot width, shall be used. Reinforcing shall be laid with main members, running at right angles to stringers. Ends of reinforcing shall be bent up three inches into curb. Strips shall be securely wired or clipped together. Reinforcing shall rest on top flange of stringers and be not more than one-half inch nor less than one-quarter inch from forms.

Concrete.—Gravel shall be from forty to sixty per cent. pebbles by weight, no stones larger than one-inch. An approved brand of Portland cement shall be used. Concrete shall be mixed in the proportion of one part cement to three parts gravel, wet mix. A batch mixer or very careful hand mixing shall be used.

Concrete shall be spread uniformly 3½ inches thick over tops of stringers. On account of stringers being of

different depths, finished roadway will be crowned two inches.

Concrete must not be trowelled, but smoothed off with a template. Curbs must be poured at same time as roadway.

Expansion Joints.—On top of every other floor beam an expansion joint shall be placed. This joint shall consist of two thicknesses of heavy tar paper.

Work shall not stop in laying the floor at any place except at an expansion joint.

Surface shall be covered with sand or sawdust and be kept wet during first five days of drying.

Forms shall not be removed in less than three weeks. No traffic shall be allowed on floor until four weeks after completion of concrete work.

Tar Top.—A skin coat of bituminous binder, mixed with sand, shall be spread on the concrete surface not to exceed one-quarter inch in thickness.

A bridge floor was replaced at Montrose, Michigan, following the above plan. The cost of doing that work, without any allowance for superstructure, was as follows:

Cost of Montrose Bridge 150-Foot Span, 16-Foot Roadway.

New 8-inch steel stringers	$ 595.00
Removing old floor	15.00
Punching and erecting new steel	60.00
Lumber for concrete forms	65.13
Labor placing forms	10.00
Cement on the job	90.00
Gravel on the job, ½-mile haul	18.00
Mixing and laying concrete	70.00
2,400 square ft. expanded metal	112.90
	$1,035.03

Itemized Cost of Concrete Per Cubic Yard.

Form lumber	$1.19 per cu. yd.
Labor on forms	.34 per cu. yd.
Cement 1:3 mix	3.03 per cu. yd.
Gravel	.60 per cu. yd.
Mixing and laying	2.36 per cu. yd.
Total	$8.52 per cu. yd.

New oak floor would cost $50 per thousand, including laying, or for a wood floor 3 inches thick, the cost would have been 15 cents per square foot, or $360. To this must be added the steel stringers needed in either floor, which makes $360 plus $595 or $955. The difference in cost of the two floors would only be $80, without any consideration of the most important item, namely: How long will it last? The concrete floor will continue to grow stronger with age, and on the other hand, the wooden floor would need repairs in five years. The concrete would tend to stiffen the whole bridge and distribute the concentrated loads over a larger area, and the wood floor is at best a springy, shaky, rough-riding and expensive proposition. An ordinary plank bridge floor weighs about 30 pounds per square foot, while the concrete floor weighs 60 pounds per square foot, both weights including steel stringers.

"When a new bridge floor for an all-steel or wrought iron bridge is needed," says Mr. Smith, "a competent bridge engineer should inspect the trusses and abutments and determine whether or not the bridge is sufficiently strong to carry a concrete floor. If the bridge is worth it or can be reinforced to make it sufficient to carry a reinforced concrete floor, it is by far the best."

THE APPLICATION OF OZONE TO WATER PURIFICATION.

IN a recent report by Russell Spaulding, consulting ozone engineer for the State Department of Health, New York, the application of ozone to water purification is treated as a process that is quite feasible commercially. The report, just issued by the Department, is very enthusiastic about the ozone process as compared with filtration which it pronounces efficient, but more or less cumbersome and not always practical; and with rapid filtration for dirt and subsequent treatment with chemicals, of which the most promising is chloride of lime.

The use of ozone as a purifying agent has received such varied publicity that the history and development of the gas needs but brief attention.

A Dutch physicist, Van Marum, in 1783, while studying the behavior of gases in the path of electrical discharges, noted that oxygen gave a decided odor. But not until 1840 was this peculiar form of oxygen recognized as a distinct gas. In that year Friedrich Schoenbein, a German chemist and professor at the University of Basel, Switzerland, showed that oxygen, after being subjected to electrical stress, possessed peculiar chemical properties. To this gas he gave the name "ozone."

The gas remained more or less of a scientific curiosity for a number of years, and the study of its properties seems not to have been attempted for practical ends until Berthelot took it up in 1890. He was followed by a long line of experimenters, most of them Europeans.

Only a few of the army of experimenters made definite contributions to the advancement of the art of producing ozone in large quantities on a commercial scale and with a minimum expenditure of power.

Ozone is a form of oxygen in which the atoms of the molecule have a different arrangement from that of ordinary oxygen. It is very unstable and will revert to oxygen in a very short time if left to itself. When, therefore, it is put into water it will speedily assume the condition of oxygen and be quite beyond the possibility of polluting water. Consequently its use is beyond any criticism which may be directed at the chemical treatment which may remain as an impurity. Ozone could not be an impurity in water, for it changes instantaneously. It owes its efficiency in acting on bacteria to the fact that it cannot remain in the condition of ozone, but breaks up and forms free oxygen, which is an extremely powerful oxidizing agent. This oxidization destroys bacteria with incredible rapidity in the purification of water by ozone, which in turn leaves no trace of itself.

The utility of ozone as a bactericide, through its marked oxidizing properties, was pointed out by de Meritens in 1886 and Froelich about 1890.

To-day there is little question of the efficacy of ozone as a commercial chemical and sterilizing agent but there are questions of practicability, related mostly to the cost of production and utilization, and to the ease of maintenance of generating apparatus. By the improvement and refinement of the generators, the cost of production has become a small part of the cost of any complete process for using ozone for purifying or bleaching. This condition arises largely through the expense of forcing contact between the ozonized air and the material to be treated.

The process about which most interest centres, naturally, is the purification of water. There are elements in the proposition to kill all bacteria and to get rid

of organic contamination by introducing "electrified air" that appeal to the popular imagination as no proposal to filter or chemically sterilize water can. It has been demonstrated that ozone is a simple and effective sterilizing agent and leaves no residue in the water repugnant to the public mind as use of chemicals would. Whether or not an ozone plant is the best thing for a given location often simmers down to a question of the costs, and these depend to a very large extent on local conditions, so that results obtained in one place are to be applied with caution to another place and only under the advice of competent engineers.

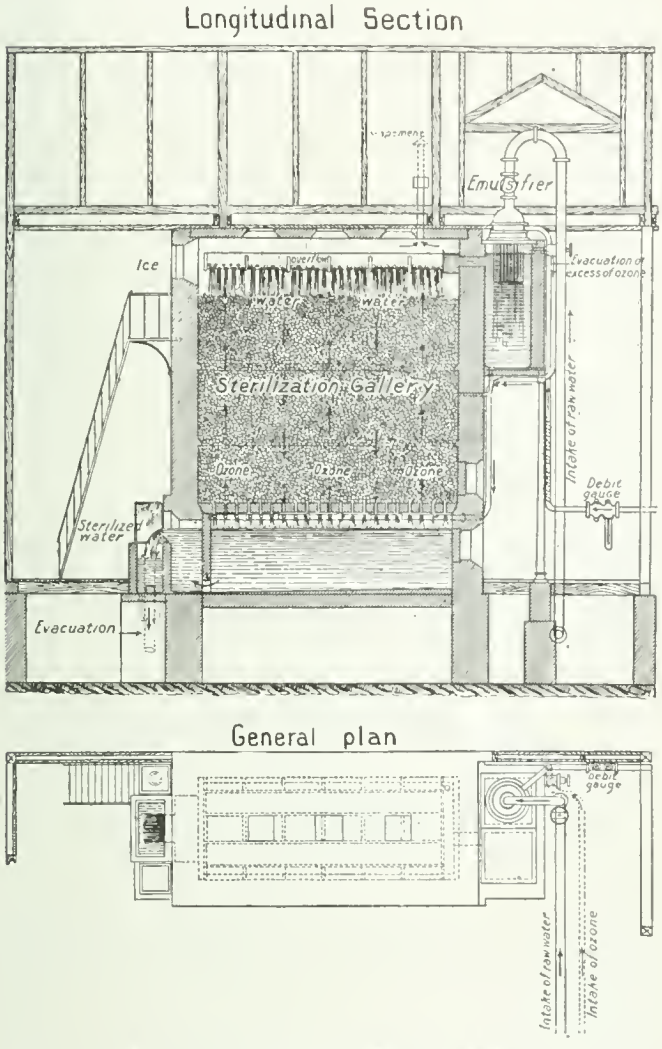

Fig. 1.—Plan of Plant at Saint Maur; Capacity 1,012,500 Gallons Per Hour.

The earliest attempt to produce and utilize ozone on a commercial scale was that of Baron Tindal at Oudshoorn in Holland, in 1893. Since then great improvements have been made in ozone-generating apparatus, both from the point of view of reliability and of economy. Baron Tindal's first apparatus yielded about 2 grammes of ozone per kilowatt hour, whereas the plants now in use in Europe produce from 40 to 50 grammes per kilowatt hour. Even this efficiency can be improved on, and the United States may soon redeem itself for its slowness in adopting a system already so well developed in Europe by outstripping the old world in the production of economical apparatus. Baron Tindal was followed by such men as De Frise, Schneller, Vandersleen, Vosmaer, Otto, Abraham, Marmier, Siemens, Gerard, each contributing to the improvement of apparatus and application. Among the European installations the systems of Otto and Siemens are giving very satisfactory service and are mentioned in the report as the best so far attained.

The list of European plants contains 26 plants in France, 4 in Roumania, 7 in Germany, 5 in Italy, 3 in Russia and 1 in Spain. Three South American plants are also mentioned. These plants range in daily capacity from 32,400 gals. for the Ravenna, Italy, plant, to 24,300,000 gals. for the St. Maur, France, plant. A brief description of several plants follows:—

Saint Maur (Paris), France.—This plant is the largest one in France, and is diagrammatically shown in Fig. 1. It was enlarged in 1910 to its present capacity of 24,300,000 gals. per 24 hours. This plant is situated near Paris on the River Marne. The water pumped from the river is first filtered through sand and then sterilized by means of ozone.

This ozone is drawn into the water by Otto aspirators. The water then trickles down through gravel contained in a sterilizing tower, meeting an ascending current of ozone which further sterilizes it. From this tower the sterilized water runs into a large reservoir, from which it is pumped into the city of Paris proper.

Nice, France.—Early in 1904 the municipality of Nice, in southern France, entered into a contract with the French Ozone Company for the erection of an ozone sterilization plant near the reservoir of Bon-Voyage. This plant, with a capacity of 6,480,000 gals. daily, was completed in 1905. The general arrangement is shown in Fig. 2.

Following are some of the requirements made by the city, translated from the official contract: 1. Capacity of sterilization, regular and continuous, 6,480,000 gals. per 24 hours. 2. Maximum allowance for upkeep $5,000 per annum. 3. The city will furnish free hydraulic power—13,157 kilogrammes on the axis of the turbines. 4. The Ozone Company guarantees that the treated water will not contain any pathogenic bacteria. 5. The maximum harmless bacteria not to exceed 10 per c.c., exception being made for B. Subtilis. 7. The Ozone Company guarantees that the chemical qualities of the water will not be altered except they be improved, that they will not introduce in the water any harmful foreign substance, and that no trace of ozone will remain in the treated water as it emits from the reservoir of Bon-Voyage. 8. The Ozone Company further guarantees the absolute innocuousness of the process. 9. The Ozone Company will be responsible for any abnormal corrosion of the conduits. 10. Price of entire installation to be $48,167.

The success of this installation is evidenced by the fact that in 1909 the community of Nice ordered installed a second plant at Rimiez with a capacity of 3,700,000 gals. per 24 hours.

Paderborn, Germany.—As a result of the experimental plants installed at Berlin in 1896 and at Martinikenfeld in 1898, it was decided to build an ozone water-purification plant on a large scale, in order to determine whether or not it would prove reliable, efficient and economical in a municipal plant.

The town of Paderborn in Germany was chosen for the initial plant. The plant was erected and officially turned over to the municipal authorities in the month of August, 1902.

The plant has a capacity of 500,000 gals. of sterilized water per 24 hours. It has been operating uninterrupt-

edly since 1902, never once failing to perform its duties in an entirely satisfactory manner. Bacteriological examinations are made regularly and at frequent intervals each day. Since the day the plant started, in 1902, these examinations have shown an entire absence of pathogenic bacteria. A duplicate of the Paderborn plant was erected in 1903 to supply the town of Wiesbaden. The plant is located near the River Rhine at Schierstein, and the sterilized water is pumped over to Wiesbaden.

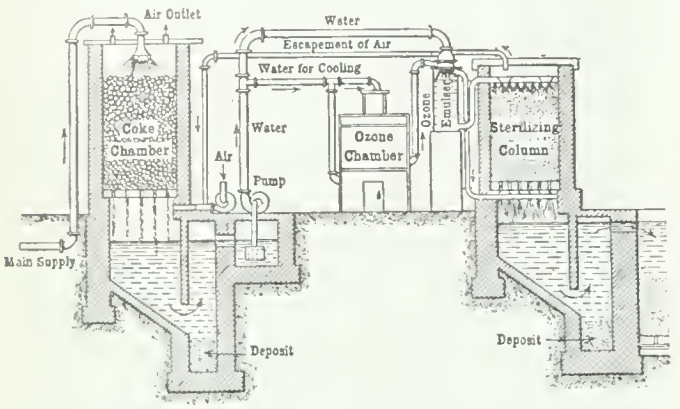

Fig. 2.—Arrangement of Plant at Nice, France; Capacity 27,000 Gallons Per Hour.

St. Petersburg, Russia.—The city of Saint Petersburg in Russia is dependent on the River Neva for the major portion of its municipal water supply. These waters were contaminated by typhoid and cholera bacteria.

After a thorough investigation of all available means for the purification of water, investigations which extended over a considerable period of time, the authorities of the city of Saint Petersburg decided that the most reliable and effective agent was ozone. Researches made at the Pasteur Institute in Paris were made the final basis of the Russian authorities.

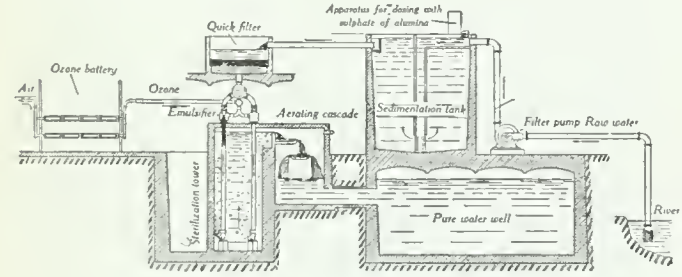

Fig. 3.—Plant at Saint Petersburg.

Work on the plant was started in 1910 and was completed in November, 1910. The water after being pumped from the river is first treated with sulphate of alumina as a coagulant; it is then filtered through rapid filters. Careful bacteriological examinations show that both before and after filtration the water contains an abundance of typhoid and cholera bacteria, whereas after ozonization there is invariably a total absence of these and all other pathogenic bacteria. The gross cost of purification, including filtration, is $15 per 1,000,000 gals. The net cost of ozone sterilization is $7.50 per 1,000,000 gals. Fig. 3 is descriptive of the installation.

In concluding his report Mr. Spaulding states that the most desirable mechanical factors to be used in connection with the generation of ozone are: 1. A supply of alternating electric current at low cost. 2. An efficient transformer to obtain high tension. 3. Ozone electrodes that do not generate enough heat to—(a) Disrupt the dielectrics; (b) Cause reversion of ozone to oxygen; (c) Require external means for cooling. 4. Ozone electrodes that will approach the theoretical efficiency much more closely than the various systems now in use.

The only failures in ozone water purification plants that have so far occurred have been due to a failure in breaking up the water in sufficiently fine particles and in properly contacting these small particles with ozone. The two failures which he mentions are those at Ann Arbor, Mich., and at Lindsay, Ont. He refers to failures in the technical sense, that is, failure to produce odorless, tasteless, colorless water, entirely free from pathogenic germs, by means of ozone. Failures might occur from a commercial point of view, because of excessive overhead charges or too high a cost of maintenance due to low efficiency or unreliability of apparatus.

The report urges upon the authorities of the State of New York the advisability of giving to ozone, as a means of purifying potable waters, their most earnest consideration, stating that there is no means known to science more reliable or absolute than ozone, with which to overcome pollution and protect public health. The latest developments of the art have brought ozone water purification well within the boundaries of economical municipal administration.

TENSILE TESTS OF CONCRETE.

A series of tests on concrete specimens measuring 18 in. long by 6 in. square has recently been made in the engineering laboratory at Cornell University.

The specimens were of three different mixtures, the first a 1:2:4 mixture containing limestone crushed to pass a 1½-in. ring, the second a 1:2:4 mixture containing sandstone, crushed to pass a 2½-in. ring, and the third a 1:2½:5 mixture containing crushed sandstone similar to that of the second mixture.

In six tests the 1:2:4 limestone concrete showed an average tensile strength of 278 lb. per square inch, the highest being 308 lb. per square inch, and the lowest 253 lb. per square inch.

In nine tests, the 1:2:4 sandstone concrete showed an average tensile strength of 150 lb. per square inch, the highest being 178 lb. per square inch, and the lowest 128 lb. per square inch.

In nine tests, the 1:2½:5 sandstone concrete showed an average tensile strength of 129 lb. per square inch, the highest being 179 lb. per square inch, and the lowest being 97 lb. per square inch.

It is worthy to note that in many instances particles of sandstone were split in two in the plane of the fracture instead of breaking the bond with the mortar; this was particularly so in the case of red sandstone, and illustrates the importance attaching to the selection of aggregates for employment in concrete work.

Boring for oil in Sicily has been vigorously prosecuted for the last 18 months, according to "Daily Consular and Trade Reports," of recent issue. It appears that there are large quantities of oil near Nicosia in Catania, containing considerable quantities of bitumen, about 40 to 55 per cent. of petroleum, and free from sulphur.

WHY SOME MUNICIPAL ASPHALT PLANTS FAIL.

By H. B. Pullar, Assoc. Am. Soc. C.E., of Pullar & Enzenroth, Engineering Chemists, Detroit, Mich.

Many cities throughout the United States and Canada now own and operate their paving plants. A majority of these paving plants have proven a success, but a number of them have been unsuccessful. It is not the intention in this paper to discuss the advisability of municipal paving plant ownership, but to show, in a manner, why some municipal paving plants fail to accomplish their purpose and prove to be a losing venture for the city that owns them. As facts are more interesting than theory, a short description of the methods used by one city owning a municipal paving plant may prove interesting.

This city, of about 50,000 inhabitants, situated in the middle eastern States, purchased a municipal paving plant and the necessary equipment for laying its own pavements, the initial capital expense amounting to about $10,000. According to the usual custom, the plant manufacturers offered the services of a so-called expert to get the plant in running order and demonstrate its economical qualities. This so-called expert, as is too often the case, was not familiar with the paving industry, and was absolutely incapable of organizing and properly running a paving plant. The city engineer, whose paving experience had been largely that of supervising the laying of brick pavements, justly became disgusted with the methods of this so-called expert and decided to operate the paving plant according to his own ideas.

Without intending to unjustly criticize the engineer and other officials in charge of this municipal asphalt plant (for without question they were running it to the best of their ability), the operation of this plant under the conditions was bound to result in a failure for the municipal plant, which eventually would disgust the taxpayers with municipal plant ownership.

The concrete foundation was laid according to the same grades and profiles used for laying brick pavements, and was in most places rough and uneven. The laying of the foundation to such grades naturally made it necessary to put down a bituminous pavement consisting of a binder and wearing surface of between 5½ and 7 inches, which, of course, was contrary to all correct and recognized principles of sheet asphalt construction. The engineer gave as his excuse for laying the foundation in such a manner that, should the sheet asphalt prove a failure, then it could be easily torn up and replaced by a brick pavement.

The paving plant was in charge of an employee who had had some previous experience in plant work, but who was not familiar with the present-day methods, and who was certainly not running the plant in an economical way. The plant site was too small, and was carelessly laid out, making it impossible to run the plant efficiently.

On account of there not being any satisfactory stone in the near vicinity, gravel was used for binder. It was used just as it came from the pit, and contained a considerable percentage of round, smooth boulders, varying in size from ½ to 2 inches in diameter. Of course, it was absolutely impossible for the binding material to hold and bind these boulders together in any satisfactory way. While this unsuitable gravel was run into the mixer from one side of the plant the asphalt cement was run into the mixer from the opposite side, the melting and mixing going on simultaneously. This is contrary to the best practice, and much better results could have been accomplished at a very small expense by having a separate kettle for melting the asphalt cement. After the mix had been running for what the foreman considered a satisfactory period it was dumped into wagons. By the time the last of the mix was out of the mixer the temperature was about fifty degrees higher than the first that came out, the result being that there was usually a part of the load that was either too cold or else overheated.

The binder was then taken to the street and laid by inexperienced men (as will later be described), to a thickness of between 3 and 4 inches. After there had been laid what was considered a sufficient amount of binder, the plant was stopped and changes made in order to run the surface mixture. No system was used in making these changes from running binder to surface mixture, and there were many useless and expensive delays.

The surface mixture consisted of sand, marble dust and asphalt cement, the sand and marble dust analyzing as follows:—

Sand.

		Per cent.
Passing mesh	200	0.0
" "	100	0.0
" "	80	0.5
" "	50	12.5
" "	40	14.0
" "	30	28.0
" "	20	11.5
" "	10	13.5
" "	4	20

Marble Dust.

		Per cent.
Passing mesh	200	80.6
" "	100	12.4
" "	80	6.0
" "	50	1.0

The marble dust was of good quality and satisfactory for filler. The sand, which was to comprise 80 per cent. of the pavement, and which is too often considered of little importance, was poor and very unsatisfactory for high-grade sheet asphalt work. As will be noted by the grading, it was entirely too coarse, and especially so when the heavy traffic of the street was taken into consideration. Sometimes it is necessary to make the best possible mix out of the available materials, but in this instance a suitable sand could have been obtained at a very small increase in cost. This poor quality of sand, mixed with too low a percentage of marble dust, was run into the mixer at the same time as asphalt cement, and, as was the case with the binder, all the materials were heated and mixed simultaneously. After the mixture had been heated for what was considered a satisfactory length of time it was dumped into wagons, the same deviation of temperature occurring during the discharge. The wearing surface after having received this improper treatment at the plant was taken to the street and carelessly laid and rolled to a thickness of between 2½ and 3½ inches.

The inefficiency exhibited by the street crew was even worse than at the plant. This crew did not contain a single man who was experienced in the laying of sheet asphalt pavements. The rakers, tampers and smoothers were merely laborers picked up in the city and knew nothing whatever about paving construction. The rollerman was inexperienced in paving work. He knew nothing at all about proper compression or the proper time to start

rolling the hot material, and he considered the pavement sufficiently rolled when it looked fairly smooth. Even a good rollerman would have had difficulty in rolling and getting the proper surface and compression to a bituminous pavement of this thickness.

Two samples taken from the pavement laid under these conditions analyzed as follows:—

		Sample 1. Per cent.	Sample 2. Per cent.
Bitumen		8.62	7.04
Passing mesh	200	4.1	5.0
" "	100	1.4	2.0
" "	80	1.5	1.0
" "	50	14.0	14.4
" "	40	29.4	27.0
" "	30	14.6	10.6
" "	20	12.3	11.2
" "	10	10.0	9.8
" "	4	12.7	19.0

It might also be interesting to note that this pavement was being laid on one of the heavy traffic streets of the city, and also on a street containing car tracks.

Just before the paving season closed this condition of affairs was brought to the attention of the city officials in charge, and after some considerable discussion, in which there was an attempted defense of the methods used, it was decided to allow an experiment to be made in laying a strip of pavement under better conditions.

The first thing that was done was to put the work under the supervision of an experienced man thoroughly familiar with the proper laying of sheet asphalt pavements. He secured a few experienced men from a nearby city and carefully watched the rest of the men, and instilled into them a little pride in the work which they were doing. On account of being very near to the end of the paving season, and the fact that it would have delayed the work considerably to get in more suitable materials for the binder and wearing surface, he took the materials which were on hand and proceeded to get the best results with them. The first thing that was done was to obtain an inch screen and screen out all the big stones contained in the gravel which was used for binder. This cost amounted to about 30 cents per cubic yard. More dust was added to the mix to stiffen it up, and the per cent. of bitumen increased to properly coat and bind the mineral aggregate. Careful attention was given to the details at the plant and on the street, temperatures were controlled as much as possible, and a fairly uniform mix obtained. A sample taken from the pavement laid under these new but improved condition analyzed as follows:—

		Per cent.
Bitumen		10.0
Passing mesh	200	6.4
" "	100	1.0
" "	80	2.3
" "	50	16.8
" "	40	14.0
" "	30	26.3
" "	20	8.7
" "	10	10.2
" "	4	14.3

The foundation was laid to a satisfactory grade, so that the pavement consisted of 1½ inches of binder and 2 inches of wearing surface. The mix was taken from the plant to the street in covered wagons, where it was handled by experienced rakers, and the rollerman was made to continue rolling both lengthwise and diagonally until the surface had the required compression and was free from marks and imperfections. Under these very adverse conditions a saving of a little over 25 cents per square yard was made in the wearing surface and a little over 24½ cents per square yard in the binder, or a total of practically 50 cents per square yard saved on the bituminous part of the pavement alone. Besides this, there was a considerable saving made on the foundation and on the grading, the details of which were not kept.

The following table gives a comparison of the amount of material and costs of construction between the work which was laid under the poor conditions existing at the municipal plant and under the adverse but improved conditions of expert supervision:—

Binder Mix.

	Weight of mix per sq. yd.	Cost per sq. yd., complete.
Old conditions	400 lbs.	$0.52
Expert supervision	188 lbs.	.2718

Top Mix.

	Sand per sq. yd.	Dust per sq. yd.	A. C. per sq. yd.	Mix per sq. yd.
Old conditions	250 lbs.	26.3 lbs.	39 lbs.	315.5 lbs.
Expert supervision	169 lbs.	21.3 lbs.	18.7 lbs.	209 lbs.

Old conditions, cost per sq. yd., complete..... $ .75
Expert supervision, cost per sq. yd., complete.. .4987

While the above example of inefficiency in running a municipal plant is, of course, unusual, and, in fact, ludicrous to those familiar with the industry, it is an accurate account of the exact condition existing in this particular city. If this poorly managed department had continued to operate their plant with their inefficient organization, tax-payers would be amply justified in condemning municipal plant ownership.

While the above example is one instance where a municipal plant will eventually become an absolute failure, there are many other municipal plants throughout the country that are not proving to be a good investment to the city, and are not being run to their maximum efficiency. There are many ways that savings could be accomplished, and if these plants were put under efficient management or someone well versed in the paving business, they would be very valuable assets for the city. For instance, a municipal plant in one of the Western cities saved over $1 per car on every carload of sand that came into their plant by merely rearranging their material and storage space, and by putting in about 50 feet extension on the side track. There are many details connected with paving plants by which much money can be uselessly expended. Cramped quarters and insufficient storage room for crude materials are an expensvie handicap, and cities desiring to install municipal plants should be careful to give proper consideration to the location.

The most common form of municipal plant failure is the one well recognized by those connected with the industry, i.e., where the city appropriates and expends sufficient money for plant and equipment to take care of all its paving, and then, on account of the laws or on account of the policy of the administration, can only run it a small part of each year for repair work. It is a waste of money for a city to invest in a plant having a capacity of from 1,000 to 2,000 yards of completed pavement per day and have only, say, 10,000 yards of repair work to be done during the entire season, and yet there are many cities owning their municipal asphalt plants where this condition prevails. In the writer's opinion no city should contemplate putting in a large municipal plant unless it

expects to use that plant for at least 50,000 square yards per year. The maintenance and cost of operation for large plants are too great, and the result is usually a failure. There are numerous small mixers on the market to-day which are satisfactory for cities who wish to do their own repair work, amounting to only a few thousand yards per year. The initial and operating costs are small, and when not in use they require practically no expense. The maintenance and depreciation are also very low.

There are many other causes for municipal paving plant failures which require long explanations, but it is at least encouraging to note that the cities owning municipal paving plants are waking up to the fact that sometimes failures can be turned into success, and are putting their municipal plants under proper conditions to do the work for which they were intended.

CLASSIFICATION OF ONTARIO ROADS.

The roads of Ontario may, for a consideration of construction, be broadly divided into three classes, states Mr. W. A. McLean, in the annual report on highway improvement, one grade merging into another, however, at the arbitrary dividing line. It is estimated that in the organized counties of old Ontario there are 50,000 miles of road, and a classification would be approximately as follows:—

1.	Trunk roads connecting the large towns and cities	5%	or 2,500 miles
2.	County or leading market roads	12%	or 6,000 miles
3.	(a) Main township roads	50%	or 25,000 miles
	(b) Secondary township roads	33%	or 16,500 miles
	Total	100%	or 50,000 miles

In the foregoing classification, the roads described as trunk roads are, with the exception of a few connecting links, among the most important of the county roads, and are heavily travelled for local market purposes, but they carry as well an increasing amount of through inter-urban traffic. The heavy and complex nature of this traffic requires, as a rule, construction of the most durable type varying from a concrete, brick, or other durable pavement to first-class macadam. The classes one and two, including trunk roads and leading market roads, thus include two divisions of what what would be the main county roads of the province. These comprise 17 per cent. or 8,500 miles in all. which if properly selected and constructed should carry 80 per cent. of the traffic of the province.

The main township roads comprise principally the concession roads on which numerous farms front and which converge into and create the traffic of trunk or county roads. The more important of these should be metalled with gravel or broken stone, if available. Secondary township roads include the little travelled connecting roads which should be graded and given such further treatment as circumstances may permit. The first need for the roads classified as township roads is thorough grading, draining and bridging, and systematic maintenance with the log drag.

Gradients adopted, amount of camber or crown, width and depth of metal, foundation if any, drainage, binding material, and other details, should, as suggested, be largely dictated by the degree of traffic. A good road attracts and creates traffic so that the construction of any one road is very likely to raise it from one class to a higher grade, a matter which should not be lost sight of in planning improvement. Methods of construction should be as simple and direct as proper results will permit. There should, for true economy, be a well adjusted average between maximum service and minimum cost.

NEW YORK CITY A VAST BRICK MARKET.

It is difficult to realize the enormous quantities of brick used annually in greater New York. During 1912 the consumption was more than 1,000,000,000. The principal source of this vast quantity is the Hudson River region, which extends along both sides of the river from New York to Cohoes and embraces ten counties, nine in New York and one in New Jersey. Other sources of supply are the Raritan River region of New Jersey and the Connecticut region.

The year 1912 was one of unusual interest in the Hudson region. It opened with an increasing demand and the price of common brick was $7 per thousand compared with $4.25 in 1911. For several years the use of cement or concrete in construction appeared to be displacing brick to some extent, but owing to the strong "back to brick" movement the year 1912 saw in the New York market a change favoring brick as the best building material for many purposes. Influences that have contributed to this change are the failure of some concrete buildings, the advertising campaign carried on by the brickmakers and the improved quality of the Hudson River brick. The average price was the highest since 1906.

The marketed product of 1912 was larger than that of 1911 and would probably have been still greater but for the scarcity of labor, especially at Haverstraw, and the strike among the brickmakers in the Newburg district. The strike was of short duration, but the scarcity of labor drawn away by large construction enterprises, such as the Catskill aqueduct, railroad extensions and subway operations, was a serious drawback to the Hudson River brickmakers in 1912. This condition was so serious that the operators resorted to night work and rainy-day work in loading barges and imported laborers from the South.

An important development during the year was a large increase in the use of Raritan River brick in New York city, which has for some years been drawing on the Raritan River region. In 1912 the demand for this brick was very much greater than ever before.

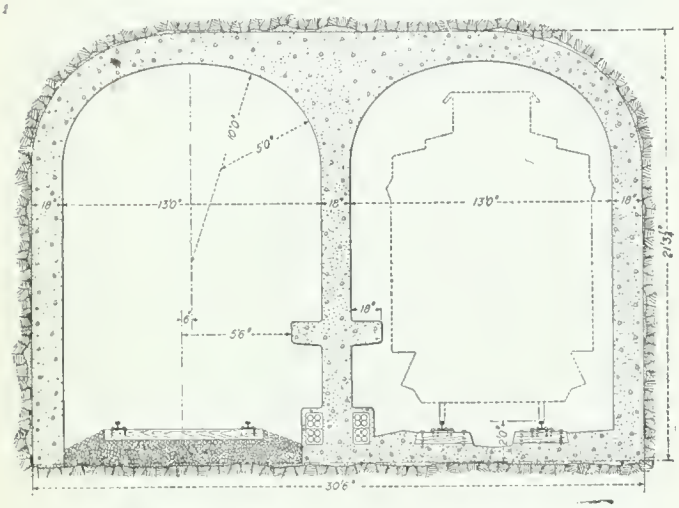
On the whole, the year may be regarded as one of prosperity. The demand was good, prices were high, the mild weather toward the end of the year permitted shipments to its close, and while the marketed product was not the largest recorded, it was considerably larger than that of 1911.

The statistics gathered by Jefferson Middleton, of the United States Geological Survey, show that the number of brick marketed in the Hudson River region in 1912 was 1,019,259,000, valued at $5,850,770, or $5.74 per thousand, compared with 926,072,000 brick in 1911, valued at $4,717,633, or $5.09 per thousand. This was an increase in 1912 of 93,187,000 brick and of $1,133,137 in value. The number of operating firms reporting in 1912 was 126.

During ten months ending May 1st Canada exported 3,250,272 tons of bituminous coal to the United States and imported in return 19,353,252 tons of anthracite and 22,356,868 tons of bituminous, according to the latest monthly summary of the United States Bureau of Foreign and Domestic Commerce.

THE CROSS-SECTION OF THE MOUNT ROYAL TUNNEL.

Various phases of preliminary and construction work in connection with the Mount Royal tunnel, to provide an entrance into the city of Montreal for the Canadian Northern Railway, have been described in previous issues of *The Canadian Engineer*. The first article, which dealt with the difficult problem encountered by the Canadian Northern Railway in arranging terminal facilities in Montreal, as the eastern distributing point for its transcontinental system, due to the location of the older and most congested part of the city lying between Mount Royal and the St. Lawrence River, appeared in the issue of January 16th, 1913. The tunnel was chosen to dispense with the necessity of making an extended detour of the city, including the possibility of two separate stations for west-bound and east-bound traffic. The location of the tunnel as then proposed was described, together with the system of tracking which it was designed to accommodate. A description of the plant to be used in this construction was also given.



Cross-Section of Mount Royal Tunnel.

In *The Canadian Engineer* for February 6th a description was given of the progress of the work upon each of the four headings which were being driven simultaneously, and general information concerning the character of earth and rocks encountered, and the methods of excavation, was included. The article illustrated the site of the tunnel, and various views of the machinery and equipment were given. An article appearing in February 27th issue dealt with the general survey work connected with the tunnel, and the methods used in precise measurements, while from time to time items of interest concerning the progress of the undertaking have appeared. The reader is requested to refer to the issues mentioned for full details pertaining to the gigantic piece of work.

It has recently developed that a twin tunnel cross-section has been adopted, of the design shown in the accompanying figure, which we reproduce from the Engineering Record. The adoption of this type is due to three especial reasons, viz., safety in case of accident or derailment, economy in excavation and construction, and economy and efficiency in ventilation. It will be noted that the new structure is similar to the tunnel work of other projects with which readers are familiar. The outside wall clearance is coincident with the clearance for the new structures in the New York Central Terminal work in New York, and exceeds the clearance of the Pennsylvania lines east of Pittsburg.

A high headroom, almost the same as that of the Detroit River tunnel, was adopted on account of the probability of a high-voltage overhead contact circuit. The flattened three-centered arch was adopted to allow for the sway of the pantograph and on account of the stratification of the rock where much of the lining will occur.

The walkway is made narrow, so that people will be forced to pass along it in single file, thus avoiding the danger of crushing and panic. The normal clearance at the walkway edge is 2 in. greater than that of the normal high passenger platform adopted in the terminal, which is somewhat greater than that allowed on the New York Central and Pennsylvania lines about New York. The walkway edge also coincides with clearance lines (outside of the platform) of the Pennsylvania lines east of Pittsburgh, including the through lines between New York and Pittsburgh.

Underneath the walkway is a continuous refuge niche, except at splicing chambers, where trackmen may sit on the duct bench at the bottom of the dividing wall and be absolutely protected from passing trains.

The work is being done by the Canadian Northern Montreal Tunnel and Terminal Company, Limited, of which Mr. S. P. Brown is chief engineer, and Mr. H. T. Fisher, tunnel engineer. This journal referred recently to 810 feet of heading having been driven in 31 days, beginning May 1st, as a tunnelling record for America. Ahead of it is a Switzerland record of 1,013 feet of 6½-ft. by 10-ft. heading accomplished in the same amount of time. The Mount Royal excavation is an 8-ft. by 12-ft. heading through Trenton limestone, which exceeds in hardness the soft triassic limestone encountered in the Loetschberg tunnel in Switzerland.

UNITED STATES PRODUCTION OF PIG IRON IN 1912.

According to a bulletin issued by the American Iron and Steel Institute, the production of pig iron in the United States in 1912 was as follows; the figures for 1911 and 1910 being given for comparison:

	1910 Tons.	1911 Tons.	1912 Tons.
Bessemer and low phosphorus	11,245,642	9,409,303	11,667,656
Basic	9,084,608	8,520,020	11,394,477
Charcoal	396,507	278,676	347,025
Ferro-manganese	71,376	74,482	125,379
Spiegeleisen	153,055	110,236	96,346
Foundry ferro-silicon, etc.	6,352,379	5,256,830	6,096,254
	27,303,567	23,649,547	29,727,137

With the development of long-distance electric-power transmission, the line voltage has increased steadily in spite of difficulties which increase at the same time. When the first 110,000-volt transmission line was put in operation, a few years ago, many considered that the maximum commercial voltage had been reached. But last year, the first 140,000-volt line was put in operation in the state of Michigan, covering a distance of 125 miles, which was soon increased to 235. The line is in regular service and is reported to be giving entire success.

EXHIBITIONS OF BRITISH GOODS IN CANADA.

The established success of the "Made-in-Canada" exhibition trains of this year and last, and the growing popularity of the enterprise throughout the provinces, is responsible for a good deal of industrial activity in many western towns and cities. The tour of the 1913 train, which terminated in Montreal a few days ago, covered some 125 points on the lines of the Canadian Pacific, Canadian Northern, and Grand Trunk Pacific roads west of Winnipeg. To practically all these places, with the exception of the larger cities, the exhibition was a new feature, having been much more comprehensive in its make-up, and having touched other points than those visited last year.

The project has aroused a lively interest outside the Dominion, especially among manufacturers in Great Britain. British Chambers of Commerce are taking up the suggestion that the best way to place British goods before Canadian customers is by the provision in Canada of a British manufacturers' exhibition train. Various chambers and associations are working upon it, in conjunction with an endeavor to urge the establishment in Canada of permanent exhibitions of manufactures from the United Kingdom.

Although of the opinion that permanent exhibitions of machinery and engineering supplies are never a success, except in so far as a unit, satisfactorily installed and efficiently operated, may and should be regarded as an exhibit, its successful operation continued under working conditions, showing the desired result, we are inclined to believe that an exhibition of British manufactures, by train, would be a good thing for Canada and Canadian industry. For instance, cars representing such manufacturing centres of Great Britain as one might mention by the score, furnished with British machinery and equipment, pertaining to municipal and public works, would create, in municipalities, conceptions not born of catalogue illustrations or literature. At the same time, Canadian manufacturers would profit by the incentive to install equipment, which these exhibitions would arouse, in the direction of electric light and power, water-supply, sanitation, and general municipal development. Besides, the spur to industry which towns have experienced as a result of the Canadian trains would, in all probability, be forthcoming from the visit of a British train, providing the tours were properly executed and the idea not overworked.

AN INSTITUTION FOR MUNICIPAL ENGINEERS.

An organization to serve the needs of Canadian municipal engineers is advocated by letter in another column of this issue. We hope its appearance will arouse a discussion of the subject. Men following this branch of the profession are peculiarly situated with regard to each other and are segregated, in fact, from engineers in general, living more or less in a sphere of their own.

A municipal engineer enjoys the distinction, however, of acquiring by necessity a general all-round engineering experience—problems electrical, mechanical, geological, of transportation, waterworks, sewage disposal, costs, estimates, etc., are all within the category of the average municipal engineer's duties. Naturally, the benefits which he would derive from social and professional intercourse with others in this work are many, tending to result in

greater efficiency of service, the elucidation of methods whereby other municipalities, in like or varied conditions, are served, and a general strengthening of the status of the municipal engineer.

Owing to the peculiar distribution of municipal engineers throughout the country—in special instances only can a few of them meet frequently—the working-up to the establishment of such an organization would be a long and arduous task, liable to prolonged lapses of inactivity. In short, although we believe that the municipal engineer would benefit greatly by such an association, it seems certain that his geographical position with respect to others in his field, together with his preoccupation with the particular needs of his own municipality, would afford him little opportunity for supporting an organizing committee in its work.

In the Canadian Society of Civil Engineers all branches of the profession in Canada should have ample representation. The society consists at present of four sections, namely, electrical, mechanical, mining, and general. A vast majority of municipal engineers throughout the country is enrolled in the membership of the society, and the well-established, coast-to-coast institution that it is, its sub-committees dealing with all engineering problems, including those pertaining to municipal work, its membership should include the entire body of three to five hundred municipal engineers estimated by Mr. Wynne-Roberts in his letter.

The establishment in the society of a section for municipal engineers would afford them the advantage of having behind it a strong, internationally recognized society, that has been serving for years all phases of the profession akin to municipal work. On the other hand, the society would be materially strengthened by having incorporated into it a section whose membership is carrying the work of the engineer into all parts of Canada, and is performing the service of connecting link between the profession and the community everywhere.

Mr. Wynne-Roberts' suggestion is good, provided the proposed association is formed as a section of the Canadian Society of Civil Engineers.

EDITORIAL COMMENT.

The Canadian Pacific Railway Company is contemplating a large extension of double track throughout Ontario, on lines both east and west of Toronto. Work is being started at once on a continuation to Guelph Junction of the double track line in use from Toronto to Islington. An extension to Detroit, 189 miles in length, is scheduled for next spring. The company also proposes double-tracking eastward to Smith Falls to link with the line from there to Montreal already in use.

* * * *

The proposed commission to investigate Ontario roads with a view to outlining a government policy for their improvement will not get an early start this season. No names have been disclosed, but Mr. W. A. Maclean, provincial engineer of highways, will likely be a member of the commission, if one may form an opinion from a recent report to the effect that Hon. J. O. Reaume, Minister of Public Works, has stated that no move would be made in this direction by the government until Mr. Maclean returns from Europe, where he is attending the International Roads Congress.

The twelfth annual meeting of the International Geological Congress, which will open shortly, should be attended by mining engineers in great numbers. The chief feature of the congress will be the numerous excursions to the principal mining districts of Canada, and to her many localities of geologic interest. The Geological Survey of Canada, the Canadian Mining Institute, and the Government are putting forth every effort to afford profitable papers and suitable accommodation at its meetings and on the numerous excursions. Cobalt, Porcupine, Sudbury, Nova Scotia, and the Yukon are among the localities which will be visited. It goes without saying that the convention will rank as the best ever held in Canada for mining men. The session in Toronto opens August 7th.

The University of Toronto's venture in discarding separate heating and lighting units in favor of a central plant for all buildings appears to have achieved vindication at last. Better service and lower cost of operation are prominent features of the report for the 1912-13 season. With the temperature 4.70 degrees above the average, for the entire season, the cost per square foot of radiation was as low as 24.153 cents, as against 38.27 cents for the previous year and 41.32 cents for 1908-09, under old conditions of separate heating units. During last year light and heat was supplied to twenty-six buildings, including Wycliffe and Victoria Colleges, containing 170,221 square feet of radiation surface, at a cost of $41,183. The report states further that by centralizing its heating systems, the University has evaded the expenditure of a large sum in the necessary renewal of individual plants, and in the installation of new systems into buildings erected during the past three years. It has, at the same time, redeemed for other urgent needs, the space previously occupied by boilers and coal bunkers.

* * * *

The International Joint Commission has before it the consideration of a proposed lease in which the Michigan-Lake Superior Power Company and the United States are the contracting parties. The power company desires to divert, for power development purposes, a flow of water from the St. Mary's River, to the extent of 25,000 to 30,000 cubic feet per second, and proposes to construct compensating works opposite Sault Ste. Marie, Mich. Under the new conservation policy adopted by the United States, the Government proposes to lease the water for power with a view to ultimately owning the development works constructed by the company. In the lease at present under consideration the latter offers to pay a yearly rate of $2.50 per cubic foot per second up to a flow of 25,000 cubic feet, in excess of which $1 per cubic foot per second is the charge it offers to meet. The question being of boundary water, and therefore of international concern, the finding of the International Joint Commission will govern the situation, and its report will be awaited with interest.

CALCUTTA SECTION, THE INSTITUTION OF MECHANICAL ENGINEERS.

The fifth annual report of the Calcutta and district section of the Institution of Mechanical Engineers has just been received. The report shows an increasing membership and a healthy contribution of interesting papers read during the past year. The membership on March 31, 1913, consisted of eighty names.

LETTERS TO THE EDITOR.

[Note.—Opinions are solicited from readers concerning subjects opened for discussion in these letters.—Ed.]

Previous Conventions in Canada of Am. Soc. C.E.

Sir,—I was much interested in reading your account of the proceedings of the recent convention of the American Society of Civil Engineers in your issue of June 26th. It recalled to my mind the first time the society met in Canada, as you rightly state, in 1881. I have very vivid recollections of that meeting—one of the most successful, socially and scientifically, ever held up to that time, and for many years thereafter.

I recall with considerable pleasure the entertainments provided the visitors and their guests—the reception at the residence of Col. C. S. Gzowski, in Toronto; the trips to Ottawa; shooting the rapids on logs at Chaudiere Falls; Rideau Hall; Parliament Buildings; Quebec; Falls of Montmorency, etc.—in charge of the Montreal local committee, headed by Mr. John Kennedy, chief engineer of harbor commissioners, chairman, with his associates, E. P. Hannaford, chief engineer of the Grand Trunk; P. Alex. Peterson, chief engineer, Intercolonial Railway: Louis Lesage, chief engineer of waterworks; Geo. Doane Ansley, city engineer, and not forgetting the noble veterans, Messrs. Thomas C. Keefer and Sandford Fleming. How many of these gentlemen are now living! The writer at that time, and for some years before and after, was chief clerk, assistant secretary and auditor of the society under Hon. John Bogart, who for many years was its most efficient and accomplished secretary.

The recent meeting in Ottawa was the third held in Canada. The convention of 1897 was held at Quebec.

THOMAS B. LEE.

Montreal, July 1st, 1913.

* * * *

A Plea for a Canadian Institution of Municipal Engineers.

Sir,—Out of about 70 societies, Canadian technical societies, 16 are associated with general engineering; 3 represent electric engineers, etc.; architects have 7 societies; land surveyors have 6; mining engineers, 3; gas engineers,. 1; railway engineers, 3; chemists, 1, and the remainder are associated with builders, astronomers, stationary engineers, good roads, smoke abatement, peat, forestry, cement, and miscellaneous, numbering in all about 18. The mayors, aldermen, councillors, and town clerks have 10 societies, organized to represent their views and wants. It is also worthy to note that there is one Public Health Association in Canada, and this is said to consist largely of medical men.

Canada is a large country, with a population of about eight million people. The health of the communities, where human activities are so pronounced, is of vital importance, yet, the last named association is the only one which has been established in this country, primarily in the interest of public health. The municipal engineers, however, as an organized, coherent body of officials, do not exist at all. In Canada, therefore, at the present time, so far as I am able to ascertain, there is no organization which has specially the right to represent and voice the views of the important profession of municipal engineers.

Why is this so? Is there a good sound reason for the absence of such a representative society? Is the immensity of Canadian territory a deterent to a prosperous institution?

After studying the situation, the writer was forced to the conclusion that it was because each municipal engineer had as much as he could do to carry on his own professional duties, and consequently, had but little time or occasion to think of such an organization. Furthermore, they dwell and work at distances, more or less great from each other, with the result that the engineer in British Columbia, for instance, rarely meets his confreres in the Prairie Provinces, much less have many opportunities of conferring with those in the East. If this applies to engineers working in the West, but whose native home is in the East, then it is still less probable that those living and working in the East get frequent opportunities for visiting works in the West. There is no inducement, at present, for them to make the trips. This, however, is not a strong reason for the absence of a Canadian Institution of Municipal Engineers, but is a powerful argument in favor of its immediate formation. The vastness of this country renders it even more desirable that engineers should combine and by means of an organized effort, eradicate the present tendency to insularity caused by their isolation from engineers in other cities and provinces.

Many of these engineers have occasion at one time or another, however infrequent, to visit other towns and cities, and to inspect various works of interest to themselves, and by making the most of their individual opportunities, they are able to secure valuable information which tends to show them that different engineers have different ways of achieving similar results. But if an insitution was formed and meetings were held at different centres, the benefits would be collective and not individual.

In the field of general engineering, there is probably an ample number of societies, and for almost every phase of engineering in Canada—except municipal engineering—there is a representative organization.

According to the Dominion census of 1911, there were 107 cities and towns in Canada having a population of 4,000 and over. This was an increase of 45 per cent. over 1901. The increase in population has been much greater during the last five years than in any other similar period, and it is safe to reckon that the number of towns and cities of 4,000 inhabitants and over will by 1921 be about 200.

Most of these towns employ an engineer, some of them also have departmental engineers, and the writer ventures to estimate that there are at present from 300 to 500 engineers engaged on municipal works in Canada, who, owing to the non-existence of a distinctively representative society, common to practically every other class of men, are left to their own resources and initiative.

A Canadian association representative of these men might include city engineers, municipal, electric, water, drainage, road, street, railway, gas, and other engineers. Perhaps consulting engineers engaged on municipal undertakings would be allowed to join. The only qualification, which would probably be needed (especially at the commencement) would be that the applicants either hold principal civic appointments or are engaged on municipal works. The members could, of course, be divided into classes according to their individual qualifications and occupations, if it was thought desirable.

Such an institution would meet in different cities, at least once a year (the oftener the better) where papers would be read by the engineers, describing the works undertaken by the city. These works would be inspected and explained, questions would be invited and answered, and a general discussion would take place.

It is ofter the case, in other societies, that a free discussion affords more useful and comparative information than is to be found in the paper itself. Such discussions are good, the weak and strong points of any scheme are brought out prominently, for in the multitude of counsel there is often much wisdom. Discussion also broadens the mind, enlarges the horizon of thought and developes the reasoning faculty; it is also educational to both the speaker and audience alike, it creates a healthy and generous rivalry, and establishes a standard of excellence which by mutual accord becomes higher each year and which will inevitably reflect credit on the profession generally, and give greater satisfaction to the public for whom we work. Such discussion would be of immense advantage to the engineers and to the authorities; the latter would not only secure an excellent advertisement, by virtue of the official visit of the society, but what is of even greater value, the town authority would hear criticisms and obtain information useful for future operations.

Later on, the institution could, if it was deemed desirable, organize examinations in the theory and practice of municipal engineering and in municipal law.

Such an institution would tend to weld together the band of municipal engineers to their own direct benefit, and the town authorities, by sending their engineers to the meetings, would in every way reap great advantages, because the educational and social aspects of such meetings would be conducive to mutual interest, efficiency, confidence, progress and *esprit-de-corps* among the officials.

Considering that enormous sums of money are annually spent by municipal engineers, of various classes, and that so much depends on the efficiency of their works in the direction of public health, public utilities, and public amenities, it might seem strange that active steps to combine had not long since been taken. An official who is perforce to follow solely his own ideas—ploughing his lonely furrow—without seeing what has been done by others in the same sphere of operations, is apt to fall behind and develop the spirit and sentiment of the proverbial cobbler who never went beyond the confines of his own little village.

Whilst in the early stages, it might perhaps, be found possible to form only provincial institutions, the formation of a powerful Dominion institution should be advocated, for in union there is strength and in co-operation there is prosperity. The aim and object of the promotion should be to force it to become a power in the land and that the opinions, transactions and developments of the institution should carry weight and tend to create an appreciative public opinion of the inobstrusive work carried on by engineers in the Dominion. Such an institution, if rightly directed and loyally supported in its initial stages, would soon reach the position when its power and influence would be felt outside the circle of engineers.

At present if any Canadian engineer desires to meet in conference, men of similar vocation, he has to cross the international boundary where, of course, he will see much to his advantage, and though he will certainly receive a warm welcome and a great hospitality, he cannot help but feel a sense of lonliness in the crowd. If, however, a representative society were to make an official visit to the same town the members would not only receive even greater welcome and more bountiful hospitality, but they would also feel far from being lost in the multitude but rather as if they were members of a great family.

From a national point of view, moreover, we should be patriotic enough to be in a position to announce that we have similar societies in Canada, for certainly we have much to be proud of in the number of municipal works, which we can visit.

The suggested Canadian Institution of Municipal Engineers, if formed, could occasionally pay an official visit to a city across the line, just as the gas engineers visited Toronto last year, and the American Society of Civil Engineers visited Ottawa recently. This is a graceful manner of recognizing the internationality of the engineering profession.

The writer does not know what are the views of the municipal engineers on this subject. He has spoken to a few and they appear to be favorable to the suggestion of forming the institution, but it will be advisable to have a free discussion before anything is done in the matter. Perhaps the editor will throw open the columns of this journal for such purpose.

R. O. WYNNE-ROBERTS.

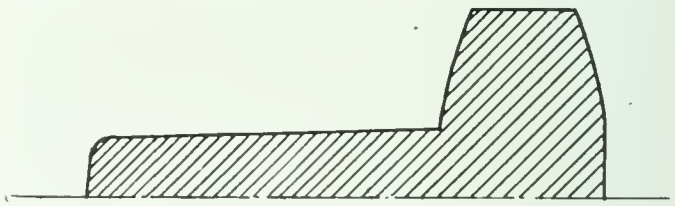
Regina, June 27th, 1913.

* * * *

The City of Toronto and the Acquisition of the Toronto Railway.

Sir,—There are several matters which it will apparently be well for the city council of Toronto to take into consideration in estimating the expenditure that will be necessary within the coming year or two, in order to bring the street railway and its equipment into such a condition that will provide a better service than is at present afforded to the citizens.

Gauge.—It must be remembered that the present gauge of the tracks is a special one, and one to which it will never pay any radial railway to construct its tracks. The gauge of four feet, ten and seven-eighths inches, was adopted in the first instance to permit vehicles of ordinary gauge to run inside the elevated portion of the rail. Even at the outset this was a mistake, because it was always a difficult matter for a wheel running upon the lower portion of the rail to be lifted out over the elevated portion, and many a wheel tire was torn off in endeavoring to get away from the track. The accompanying figure shows the form of the original rail.



It is necessary, therefore, for the city council to bear in mind that the gauge should be changed now that there is an opportunity. It should never have been permitted to remain in use when the railway discontinued horse in favor of electric traction.

This change necessarily requires a certain amount of alteration in the tracks, and while this is being done is a most opportune time for widening the space between them, i.e., the devil strip. The necessity of this change has been so self-evident that new tracks and new diamond crossings have already been laid to a greater width than previously, in readiness for this contingency.

Wide Devil-Strip Necessary to Accommodate Cars of Radial Railway.—The actual width between new tracks at present is not known to the writer, but from observa-

tion it appears to be too small. He found, when constructing an interurban railway, the cars of which were to be run through the streets of the City of Rochester, N.Y., that the devil-strip there, of four feet in width, was too narrow to admit of cars of suitable width for longer journeys than are usually taken on the street railway. As far as possible, therefore, the cars for radial railways which must be constructed sufficiently wide for comfortable seating, will be run over streets that have only a single track laid upon them, unless there is a suitably wide devil-strip on double-tracked streets.

After much consideration the City of Chicago decided, last year, that in streets with double tracking, the distance of the tracks from centre to centre should be ten feet two inches, leaving a clear space of twenty inches between two cars, each eight feet six inches in width, so that all classes of cars could be safely moved upon them.

In order to have a suitable width in the seating of the Rochester Street Railway cars, when there was a central aisle there was a double seat on one side and a single seat on the other—a very poor arrangement, but one occasioned by a devil-strip only four feet in width.

Naturally these changes will require considerable expenditure on capital account, there being, of course, items of labor and new materials required in the alteration of the track gauge.

Central Aisles in Cars.—The trucks of existing cars will likewise require alteration and many cars should now be scrapped, the annoying "wet curtain" cars first of all, and others of modern standard construction provided to replace them. The very undesirable system of longitudinal seats should be done away with in any cars, such as those of the convertible type, that are sufficiently wide to admit of a central gangway.

Low Floor Cars.—A number of Pittsburgh low floor cars should at once be put into commission, to obviate the unnecessary climb which now exists in Toronto cars, and which is so trying to many ladies, to children, and to infirm persons of both sexes.

P. A. Y. E. Cars.—There is no reason why all cars should not be prepared for the pay-as-you-enter system, so as to be ready as soon as the system is adopted on all routes.

The above items are only a few which suggest themselves as points of engineering importance. There are many more which will naturally occur to those familiar with the operation of a city service. Existing methods show abundance of room for improvement.

It would not be surprising if, after acquiring the properties now under consideration, at a cost of $29,000,000, a further outlay of $11,000,000 were required for the lines which are already in commission, and for the necessary alterations to existing track and equipment. It would seem prudent, therefore, for the city council to provide for a total outlay of $40,000,000 accordingly, when making the requisite financial arrangements.

EDMUND WRAGGE.

Toronto, June 24th, 1913.

* * * *

Sir,—According to the Calgary newspapers, I note that the city of Calgary is considering piping water from a point forty-five miles distant.

Calgary is growing greatly and I presume that they would not install less than a 50-inch main. This would make the cost great. It is surprising, particularly in view of the financial conditions in Western Canada, that this proposition would be considered seriously, in view of the fact that a twenty-million-gallon filtration plant, sufficient to supply the city of Calgary for several years to come, could be installed complete at a cost not exceeding $400,000.

The operating cost of such a filter plant would not be as great as the interest on the difference in cost between the filter plant and the pipe line. Furthermore, there is the large item of patrolling this line and keeping it in shape, and the possibility of the source of supply not being sufficient or becoming contaminated and subject to a period of turbidity in future years. The city officials of Calgary will do well to consider this matter thoroughly before going ahead with it, and should certainly secure the best possible engineering advice.

WATERWORKS ENGINEER.

Winnipeg, June 26th, 1913.

ROAD INSPECTORS IN NEW ZEALAND.

Judging from the schedule of duties, with a copy of which a correspondent, resident in New Zealand, has recently favored us, and which appears below, the position of road clerk, or overseer, in some municipalities of this antipodal sister colony, is not without a full course of obligations.

(1) The clerk and overseer to give all his working time, i.e., eight hours per day on six days of the week, to the service of the board, excepting statutory holidays, or holidays given by the board or its chairman for the time being; such working time to be spent in such manner as the board shall instruct in connection with the carrying out of office work and the inspection of roads, etc., and other necessary work.

(2) To do all the clerical work in connection with the business of the board, i.e., to carry out all necessary correspondence, keep all accounts, and prepare all necessary specifications and estimates.

(3) To do all surveying and measuring in connection with, and superintend all works and contracts carried on or let by the board, also to inspect frequently and report upon, monthly at least, all roads, etc., under the control of the board, and to carry out to the satisfaction of the board all the usual duties of a clerk and overseer to a road board.

(4) When on his rounds of inspection of roads and supervising the work of the board's employees, or contractors, the clerk to carry with him suitable tools for effecting small repairs to roads, fords, etc., such work to be carried out by him as the time at his disposal will permit.

(5) The clerk to provide his own horse or horses, vehicles, harness, necessary for carrying out the above duties.

(6) The clerk shall not undertake any work or duty of whatsoever kind other than that of the board, without its consent

(7) The clerk shall, beside his other duties, perform the duties of poundkeeper.

(8) The clerk to be paid by the board a salary of £200 (two hundred pounds) per annum, with free use of house, outbuildings, stables, garden and balance of five acres of land.

(9) The clerk to enter into a fidelity bond in the sum of £300. The premium of such bond to be paid by the board.

(10) One month's notice to terminate the appointment to be given by either side.

THE SCIENTIFIC UTILIZATION OF NATURAL RESOURCES.*

By Dr. W. W. Andrews.

In these days of modern development conservation has come to be a great work. As a people, we have marched across this continent, skimming its resources in most wasteful ways. This has been called "the White Peril" of the world, for we are found under every sky, wastefully exploiting nature's gifts to the race. A method of agriculture which over large areas has robbed the soil of its fertility, and a method of lumbering which has taken no care of the younger trees, with frequent forest fires destroying millions of dollars worth of timber, have hardly troubled our consciences.

During the last few years, however, a more enlightened sense of values has been making itself felt. In some businesses the dump heaps of former years have become the great sources of profit. We have further begun to realize how enormous are the resources lying unused and wasted around us, and the best powers of science are being devoted to the task of finding the best means of putting these to human use.

So rapidly are we laying under contribution the forces of nature, increasing human efficiency by millions of horse-power and lifting burdens from human muscles, that we may hope very soberly for the time when the manufactured wealth of the world will be so great that drudgery will be almost totally eliminated from human life, and the wealth produced through these borrowed powers be so abundant that poverty will be practically unknown. All that remains after physical science has done its work is that social science shall lead us to a condition of society in which wealth will be more evenly distributed than it is at present. The promise of this is already above the horizon.

The physical resources of a country are limited and unrenewable. Such are coals, our gold, iron and all other mineral deposits. The more rapidly we exploit these the sooner they are used up, never to be at the service of the world again. The ancient bituminous and anthracite coals, and the modern lignites can never be restored. Why should we be in so feverish a haste to use up these assets of the world which belong to future ages as well as to ourselves?

The second class of resources are those which are perennial and exhaustless, because they are perpetually renewed, such as growths of our fields and our forests, the flow of our waters, and the force of our winds. All these depend upon the force of the sun, and from year to year they are reproduced. Emerson said: "Hitch your wagon to a star," and that nation which builds its prosperity on a wise utilization and conservation of these resources may keep its population and its prosperity as long as the sun shines.

Utilization of the Wind.—The first of these of which I shall speak is the force of the wind. The difficulty in using this force is found in the fact that it is a widely diffused force, and is fitful in its operation. If we can economically capture it and store its energy so that it will be at our call whenever we wish to use it, it may be made of immense service.

The winds of Saskatchewan are nearly equal to a nine-mile breeze blowing day and night from June to June. The total force of this is equal to a thousand Niagaras. Can it be utilized? It is interesting to note in these days of the supremacy of steam power that of the forty thousand vessels which comprise England's merchant marine, thirty thousand are yet wind-propelled. It was the wind power which carried the Anglo-Saxon Celt around the world, and it is seen that he is depending in a large measure upon it still. I call your attention to the following recent developments. It has been found that a comparatively slight change in the shape of the fans in a wind motor will give almost double the power. It has further been shown that the wheel of a hydroplane working in the air is more efficient than a wheel working in the water. If, therefore, these two discoveries are made good use of, we may expect to find very much more efficient wind motors than we have known heretofore.

The development of the storage battery is being rapidly promoted, and the increasing efficiency of dynamos points to a time when the energy of the wind will be economically stored. We have all heard of the Edison storage battery, which may be charged and discharged at any rate without injury to the battery. In the common lead battery Prof. Hannover, of Copenhagen, has discovered a method of making what he calls "pore" lead, which increases the capacity of a battery about four times. On the basis of such advances as these we may look for the time when the electric automobile will be the common automobile throughout the country, and wind stations, with their installation of windmills, will be as marked features of the prairies as the grain elevator is at present.

Clay Resources.—The next great asset of this country of which I shall speak are our practically omnipresent clays. These clays have been produced from the original granites of the earth, through the action of water, rain, and moving ice, and by streams they have been deposited in their present beds. They are thus produced indirectly by sun power throughout millions of years of the earth's past history, and are being produced and laid down today. They therefore belong to the exhaustless resources of the world, even though their quality was not as great as it is. The clays of these prairie provinces will yet prove to be, after the fertility of the soil, the most useful asset of the people. Their variety is so great, the new methods of manipulating them is so efficient, that there are but few of them which cannot be put to commercial use. Structural material, such as wood and iron and stone, will always be dear in these prairie provinces. In the clays we must find our substitutes. Leaving out of account the Portland cement, which requires lime, in addition to the clay, we need only speak of the use of the clay for building purposes, in the form of bricks, tile, pillars, decorative panels and pottery, and for road-making purposes.

I could show you some specimens of bricks and pieces of pottery, which have been made out of clays which were deemed to be almost hopeless. When this much can be realized with these, we may speak hopefully of all other clays. In China the clay-workers of one generation dig the clay for the next. Modern methods enable us to produce an equal amelioration of the clay in ten days, instead of thirty years. Each clay-bed, however, needs to be subjected to careful experimental tests, and this should give results definite enough for wise investment.

We all know what a trial our clay is when wet, to those who try to haul loads along our roads. It has been

* Read at the 8th Annual Convention of the Union of Saskatchewan Municipalities, June 26th, 1913.

found that if we subject the clay, which has been compacted somewhat by road traffic, that if it be piled up in beehive shape kiln, and well burned, we get a material devoid of all stickiness and in its smaller particles very hard, and quite porous to water. This substance will grind under traffic into a dust. But this may be counteracted by a judicious mixture of raw clay.

The experimental road which was laid down for the government was built in this manner. A narrow trench was dug along the centre of the road. In this a tile drain was laid, and then covered in with burnt clay, hammered down. Then a layer of straw was laid over the clay of the road, and over that eight inches of burnt clay containing 25 per cent. of raw clay was laid over the surface as the road metal. The whole was then well rolled with a heavy roller. This portion of road is standing up well under traffic, dries quickly, does not load the wheels, and is showing the same properties which most of you are familiar with in many parts of the country where sand and clay have been mixed by nature in such proportion that bad roads are seldom found. All such a road needs is that it shall be dragged after every rain with a split-log drag. It looks as if it could be depended upon to give a clean, satisfactory road at all seasons of the year. It is very easy also to treat such a road when it is wet, by hauling over it either the split-log drag or the lap-drag backwards.

Another suggestion which I have made has not yet been put to experimental test. I have thought that the marble-like hardness which our gumbo acquires, when it dries under traffic, could be made use of to give us a firm foundation for asphalt roads, in place of the costly concrete. Certain it is that if water be kept out of it, it will stand the heaviest kind of traffic, even without the protection of an asphalt sheet. To conserve the hardness of the gumbo base, I suggest the laying of a central underdrain with cut-offs to the side ditches, so placed that whichever way the wind blows they may cause a movement of dry air through the heart of the road. I am in hopes that some form of this road will make the asphalt road cheap enough to become a country road proposition, at least on those roads which are subjected to the heaviest traffic.

The burnt clay, when properly prepared, is found to have the properties of good sharp sand. It may, therefore, replace sand in ordinary mortar. Word has come that the British Government specify this for some of the work done in India. A homesteader, therefore, may out of the clay dug from his cellar find a substitute for sand. This ought to prove of great value to homesteaders who are miles away from a good sand-pit.

A little special treatment will also produce a very fine material which can take the place of costly broken stone in asphalt and concrete work.

Fuel Production.—The last subject before you is that of the possible utilization of the great stores of fuel which we have in the straws which are burned in so immense quantities each year on the prairie.

Various authorities state that the amount of combustible gas in straw amounts to twelve thousand cubic feet per ton. The writer's measurement, without being made very exact, supports this estimate. Personal analysis of the straw shows the following:—

Volatile hydrocarbons, 64 to 72 per cent.
Moisture, 6 to 10 per cent.
Fixed carbon, 21 to 24 per cent.
Ash, 6.5 to 8.2 per cent.

If 25 to 30 per cent. of the volatile matter be driven off, that is, the moisture and the hydrocarbons, we have a slightly charred mass, which is very brittle, is very similar in composition to good dried lignite, and has a calorific value of eight thousand seven hundred B.t.u. This I have named "Lignite Char." If 70 per cent. of the weight be driven off, in the form of volatile matter, then a char similar to anthracite in many of its qualities, and of very similar chemical composition, is left as a residue. This I call "Anthracite Char." Both of these residues can be readily made into briquettes, named respectively "straw lignite briquettes" and "straw anthracite briquettes." It is possible to manufacture any grade between these two extremes.

The purpose of this study was to find whether it is possible to make a portable machine which would go from farm to farm, after the manner of a threshing machine, and using the materials on the farm, manufacture a farmer's fuel. It is found that the slight charring of straw solves the problem of reducing the straw to a powder fine enough for briquetting, and also that pulped potatoes forms an excellent material for binder. Beet sugar waste also is a very satisfactory binder. One ton of straw will produce 1,400 pounds of briquettes. If we allow 400 pounds to be used up in producing the charring of a ton, then one ton of straw will yield a thousand pounds of fuel. If we count the yield of straw as one ton per acre, then one-half section of wheat or other grain will yield 160 tons of fuel, equal to the best lignite. Three acres of potatoes will supply sufficient binder for this quantity. It will thus be seen that the farm may not only produce all the fuel necessary for household and power purposes, but the small towns or villages may be supplied with fuel from the neighboring farms. As the fuel may be cheaply produced, it opens up the possibility of cheap fuel, and therefore of small manufactures through the province. Wherever the homesteader goes, there can be found his fuel without haulage and freight charges.

How enormous the possibilities are will be shown from the following: Suppose we think of a square forty miles each way, with Regina as the centre. If 24,000 acres be left out for the city and vacant places, and supposing that one-half the remaining area is given to grain crops, 250,000 tons of this fuel may be produced every year for all time, nearly all of this coming a distance of less than twenty miles from the city.

The importance of this kind of work must be evident to all. If it is done, it must be thoroughly done, and with fully adequate equipment. I need scarcely appeal to the members of this influential body to heartily support the government to carry on this kind of work, whether it be directly under government auspices, or by the university. In the work that I have done, the discovery that our clay would make a substitute for sand at a cost of 50 cents per cubic yard, as against $1.80 to $2 for natural sand, when it comes to be used as largely as it may, will repay many times over every year all that these initial researches have cost. All future development must depend first of all on the application of scientific research and scientific principles to the problems which arise in connection with the development of the enormous resources of a province such as this. No investment of money can pay as well.

More durable and elastic than ordinary macadam is said to be a new pavement laid in Paris with a bottom layer of concrete, an intermediate one of concrete mortar reinforced with iron rods and a surfacing of crushed stone and mortar.

REINFORCED CONCRETE PONTOONS FOR A MODERN FLOATING BOATHOUSE.

By D. C. Findlay, B.Sc., A. M. Can. Soc. C.E.

The universal presence of the "teredo" in the salt water of the ocean renders very short the life of wood used for supporting floating boathouses, etc. Likewise, steel pontoons require special surface coating and frequent inspection to ensure against their being corroded by the salt water.

In the design of the modern boathouse described below, concrete was used for the novel purpose of building the pontoons, as it is unaffected by either, if properly constructed. Fig. 1 shows the outside form assembled and the reinforcing in position. The walls and floor are only 2½ inches thick and consequently the design and installation of the reinforcing required great accuracy and care. Half-inch square bars were carefully bent to the shape of the shell, carried along the bottom and up the sides. These bars were spaced about 18 inches centres, and the ends of longitudinal ½-inch bars were carefully looped to accurately fit the ½-inch vertical bars. One of these bars was driven down with a sledge until it was 1 inch from the bottom on each side. A second bar was placed on the top on either side and across the ends. This

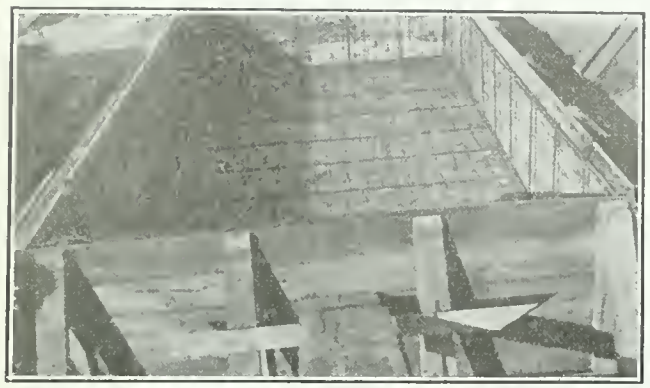


Fig. 1.—Pontoon Form Showing Reinforcing.

formed a very rigid skeleton steel frame of interlocked bars which could not be displaced, and which afforded ample support for fastening the intermediate bars in position. On this framework was carefully spread triangle wire mesh, style No. 26. The lengths were cut and formed so as to extend along the bottom longitudinally and up the two ends, and the sides were treated likewise. The wire mesh was carefully wired to ½-inch bars at every intersection. At about 20 inches from each end a special reinforcing bar had an eye welded to it, projecting above the top of the finished side wall. This enabled chain blocks to be applied for launching, and furnished means of attaching ropes for towing to the site of the boathouse.

This building is 100 feet long by 27 feet wide with a clear height of 17 feet 6 inches to the bottom of the roof truss. Calculations to ascertain its weight determined the most economical size of pontoon to be 16 feet long by 7 feet 6 inches wide and 30 feet deep.

Fig. 2 shows one of the finished pontoons in the water after launching. A centre partition was built into the side walls and floor and consisted of "ferro-dovetail" sheets with their ends projecting 1½ inches into the walls and plastered with concrete on both sides. This stiffened the walls and made two separate water-tight compartments.

For attaching the sills of the boathouse ¾-inch bolts, threaded at the ends, were set into the concrete about 3 inches off the centre of the pontoon, to which the 6-inch by 8-inch sills of the boathouse were bolted. This offset was calculated sufficient to withstand the extra weight of the roof slab and to cause the pontoon to float properly in the water.

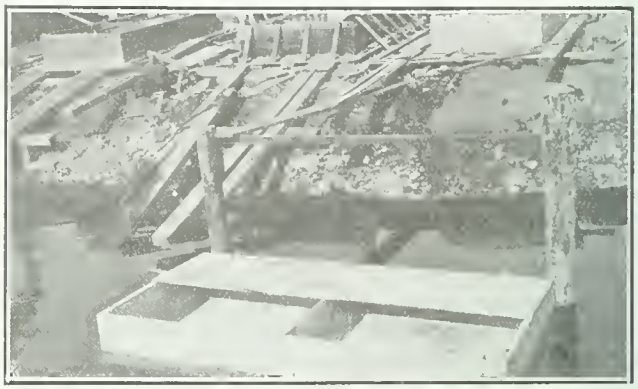

Fig. 2.—Finished Pontoon.

It may be noticed that the roof slab extends on one side only. Further, the end walls were cast with a 2-inch fall from the centre. This portion of the pontoon is outside the building line and the roof sheds the rain. The roof is made of "ferro-dovetail" sheets ⅝-inch in depth of groove, resting on the centre partition wall, and fastened to the ends and side by ⅜-inch carriage bolts placed in the green concrete. Both top and bottom of the sheets were then plastered with a 1:2 mixture. The finished roof slab was only 1¼ inches thick, but possessed remarkable strength and absolute watertightness.

In order to get all the buoyancy possible, every pound of unnecessary weight had to be eliminated. As constructed, the pontoons weighed about 8,000 lbs. and, on launching, floated to within ¼ inch of calculated water line. Each pontoon supports a live load of about 7,800 pounds.

The boathouse under description has 11 pontoons under it, five on each side and one on the forward end, while the other end of the building, containing the large swinging doors, as shown in Fig. 3, was tied together by a 1½-inch iron bar attached by galvanized bolts to the top of the pontoon, and passing between guide bolts set in the bottom, so as to distribute the load in a vertical plane. The horizontal part of the tie rod was 6 feet below water, allowing a yacht to pass over it in entering the boathouse.

The building is rigidly built, and the roof supported by trusses, both roof and walls being covered with a special V crimp, galvanized iron, with a panelled lattice running around the entire building. Manholes in the floor allow for inspection of the inside of the pontoons, which are used for storing light material used about the yacht. At one end it is held in position by a reinforced concrete pile 24 inches square, and by a floating boom attached to the shore at the other. A floating fender attached by spreaders to the sill was installed to prevent the yacht ramming the pontoons in making a landing alongside the boathouse.

In constructing the pontoons, 3 casting floors of shiplap were built on the beach and carefully levelled up. These served as forms for the bottom of the pontoon and two sets of collapsible wood forms were then made up, which were used 15 times in all. The outside forms were first set up and the reinforcing carefully placed and supported from the bottom by small concrete blocks which were cast into the floor. The floor was then poured, using a wet mixture of 1 part cement and 2 parts sand. This covered the steel completely, and was very thoroughly tamped to fill all the voids.

A mixture of 1 part cement, 2 parts sand and one part screened gravel of ½ inch maximum size was then poured on the top and brought to a depth of 2½ inches. The collapsible inside form was then quickly set in place, and braced into alignment, and the concreting of the walls continued without a break. Very great care was used in the mixing, and especially in tamping the thin walls, to insure the steel being thoroughly enclosed and all air expelled. Very gratifying results were obtained, as of the 15 pontoons built, not one of them showed any indications of dampness of any sort when launched. They have been in the water now for nearly nine months.

Fig. 3.—Showing Pontoons in Place.

Forms were stripped in about 36 hours and allowed to season until thoroughly set, when a frame was placed over each end. Chain blocks were used to lift the pontoon clear of the floor, when launching timbers 10 by 14 inches were placed under on rollers. At high tide the pontoon was about 6 feet above the water. An incline runway was built, extending into the water, and a temporary roof built over the open side of the pontoon to prevent shipping water on launching. Two men with bars easily pushed it off the floor and it took the water very easily. A motor boat then took it in tow for about a mile to the site of the boathouse.

Accurate account was kept of the cost, which amounted to $78 including launching, for each pontoon.

Considering their indestructibility, they are far superior to anything else in use, and prove conclusively that concrete itself, if well placed, is a sufficient waterproofing agent, as no waterproofing was used in the concrete.

The pontoons and boathouse were designed and built under the direction of Mr. D. C. Findlay, A. M. Can. Soc. C.E., chief engineer of the Vancouver Portland Cement Company, Limited, of Victoria, B.C., for Mr. R. P. Butchart, managing director of the company.

MACADAMIZED ROADS CONSTRUCTED WITH TARRY, BITUMINOUS OR ASPHALTIC BINDERS.

At the third International Road Congress the third question, "Construction of Macadamized Roads Bound With Tarry, Bituminous or Asphaltic Materials," was discussed by representatives from twelve different countries. Interests on this side of the Atlantic were looked after by Professor A. H. Blanchard, of Columbia University, and consulting engineer of New York; Major W. W. Crosby, chief engineer to the Maryland Geological Survey, and consulting engineer of Baltimore, and Prevost Hubbard, Department of Roads and Pavements, the Institute of Industrial Research, Washington. The following is taken from Professor Blanchard's paper, which dealt with bituminous surfaces and bituminous pavements constructed by the mixing methods, and refers to progress made during the past three years:

In order to avoid continual explanations and the use of long expressions, the following definitions are given:

Bituminous surfaces consist of superficial coats of bituminous materials with or without the addition of stone or slag chips, gravel, sand or materials of a similar character.

Bituminous concrete pavements are those having a wearing surface (crust) composed of stone, gravel, sand, shell or slag or combination thereof, incorporated together by mixing methods.

Bituminous concrete pavements which have been used in the United States during the past three years and of which broken stone forms an integral part may be grouped in three classes dependent upon the character of the mineral aggregate.

Type A consists of so-called one size crusher run broken stone mixed with bituminous material. This description of broken stone refers to the product obtained at a crushing plant which passes over a screen having holes of one size and through a section of screen having the next larger size holes or which passes through a screen of one size of holes and is retained upon a screen having smaller holes.

Type B consists of one size crusher run broken stone as defined above and sand or other fine mineral matter mixed with bituminous material.

Type C consists of a predetermined graded aggregate usually composed of broken stone and sand with or without other mineral matter mixed with bituminous material.

Foundations and Drainage.—The following statements contained in the 1912 Report of the Special Committee on "Bituminous Materials for Road Construction" of the American Society of Civil Engineers embody the underlying principles of the best current practice relative to foundations, subdrainage and surface drainage.

Sub-Grades and Foundations.—Your Committee believes that the use of any form of a bituminous wearing surface does not preclude the necessity for the construction of a well-drained, thoroughly compacted and adequate sub-grade. In fact, such improvement of the road surface frequently attracts heavier traffic, and thus increases the stresses in the sub-grade.

Crown.—The investigations and observations of the Committee to date have convinced it that the crown generally used in construction of macadam roads is excessive when bituminous materials are used, and that a crown of even ½ in. to the foot should be avoided when a lesser

crown can be secured without detriment to the surface drainage.

The above report will hereinafter be designated as the "Am. Soc. C.E. 1912 Report."

Sizes and Shapes of Broken Stone for Bituminous Bound Surface Crust.—Bituminous surfaces have proved more efficacious when constructed on macadam roads composed of well compacted and thoroughly bonded broken stone ranging from ¾ in. to 2 ins. in the wearing surface than when the stone is of smaller dimensions. This size of stone is usually obtained by passing over a screen having 1¼-in. holes and through a screen having 2¼-in. holes.

Bituminous concrete pavements. Type A.: The best results have been secured by using a mineral aggregate composed of broken stone varying in size from stone passing a 1¼-in. laboratory screen to a small amount passing a ¼-in. screen. This product is usually obtained from the ordinary type of crushing plant from stone passing over a ½ or ⅝-in. screen and through a section of a screen having holes 1¼-in. in diameter. A typical analysis of such a product follows:

Per cent. passing ¼-in. screen	5.4
Per cent. passing ½-in. screen	34.7
Per cent. passing ¾-in. screen	40.6
Per cent. passing 1 -in. screen	17.3
Per cent. passing 1¼-in. screen	2.0

The following excerpt from the "Am. Soc. C.E. 1912 Report" bears especially upon the construction of Type A.:

Your Committee recommends that trap rock in sizes greater than that passing a 2-in. screen should be used with caution in the construction of the upper course, unless the voids of the same are properly reduced, because of the liability of the individual stones to rock under traffic.

Type B.: The mineral aggregate has been composed of a combination of one size crusher run broken stone and one or more grades of sand or stone screenings. The mechanical analysis of a typical combination covered by the description, two parts trap rock passing a 1¼-in. ring with a maximum of 5 per cent. dust and one part sand, follows:

Per cent. passing 200-mesh screen	3.3
Per cent. passing 80-mesh screen	6.9
Per cent. passing 10-mesh screen	29.7
Per cent. passing ¼-in. screen	25.1
Per cent. passing ½-in. screen	24.3
Per cent. passing ¾-in. screen	10.7

Type C.: One class of mineral aggregate which has been used to a considerable extent during 1911 and 1912 is known as the "Topeka" grading and is usually composed of broken stone and sand with or without a filler of fine material. The grading for this mixture is covered by the following limitations in the mechanical analysis:

Per cent. passing 200-mesh screen	from 5 to 11
Per cent. passing 40-mesh screen	from 18 to 30
Per cent. passing 10-mesh screen	from 25 to 55
Per cent. passing 4-mesh screen	from 8 to 22
Per cent. passing 2-mesh screen	less than 10

Many bituminous pavements of Type C with proprietary names are laid in the United States. Among these may be mentioned "Bitulithic" and "Warrenite."

Use of Partially Worn Materials in Bituminous Bound Surface Crust.—The universal practice has been to condemn the use of materials, which have been previously employed, for the mineral aggregate in the construction of bituminous concrete pavements.

Thickness and Composition of the Strength Crust and of the Super or Wearing Crust Under Different Conditions.—Bituminous surfaces: A thin coat of the proper kind of bituminous material has given better satisfaction than the formation of a comparatively thick carpet, especially when the surface is subjected to excessive horse-drawn vehicle traffic.

Bituminous Concrete Pavements: Type A is usually laid upon a foundation course of broken stone having a thickness varying from 4 to 8 ins. Type B is laid on a broken stone foundation course as indicated for Type A or a cement concrete foundation, 5 to 6 ins. in thickness. Type C is laid on a broken stone or a cement concrete foundation as mentioned for Type B. It is being recognized as a fundamental principle that where Type C is used under conditions which render it economical and suitable, only the cement concrete foundation should be employed. The necessity for constructing strong foundation courses due especially to the rapid development of motor truck traffic is apparent. For Types A and B the thickness of the wearing surface has varied from 1½ ins. to 3 ins., the average being 2 ins. For Type C, when a fine mineral aggregate is employed, 1½ to 2 ins. has been used, the best practice favoring 2 ins. Pavements with mineral aggregates having larger broken stone are generally laid 2 ins. in thickness, although 3 ins. has been used in some cases.

Life of Surface Crust Under Different Conditions of Traffic, Weather, Subsoil, etc.—Bituminous surfaces: The life depends primarily upon the character of the material and the amount and kind of traffic. Bituminous surfaces on macadam roads have a life of from one to three years and on bituminous concrete pavements from one to five years.

Bituminous Concrete Pavements: As with all types of bituminous pavements, the life of the wearing surface depends, to a large extent, upon the character of maintenance. Granted proper construction, including adequate foundations and drainage, and continual maintenance, which includes the use of seal coats applied periodically, the life of bituminous concrete pavements, based upon such information as is at hand, may be estimated at from 20 to 35 years. This estimate is based upon the supposition that the various types of bituminous concrete pavements are used under conditions for which each is suitable. More definite information is at hand covering the life of pavements which have not been maintained. The following estimates cover average life without maintenance: Type A, 4 to 10 years; Types B and C, 7 to 15 years.

Relative Importance of Patching, Repairs and Periodical Renewals of Surface Crust. Extent of Wear Permissible Before Renewal of Surface Coating.—All types of bituminous surfaces and pavements are liable to develop weak spots. Patching in these cases is found to be economical and practical as it is comparatively simple to replace a portion of a bituminous concrete pavement or a macadam road. Likewise periodical renewals of bituminous surfaces are efficacious. This method of repairing will be economical until such time as the pavement begins to generally wear out or disintegrate.

Measurement of Wear and Appliances Used for This Purpose.—Work of this character on bituminous concrete pavements has been limited to that of a few investigators,

all of whom have used the method of periodically taking accurate elevations in order to determine the amount of wear.

Various Methods of Bituminous Treatment. (a) Mixing Methods.—(1) in Factories; (2) on the Spot.—Type A.: In 1910 practically all of the bituminous pavements of this type were constructed by hand mixing methods. In very few cases was the broken stone heated. During 1911 and 1912 there has been a general abandonment of hand mixing methods and a substitution therefor of various machines especially designed for the heating of the mineral aggregate and the mixing of it with bituminous materials. The introduction of these machines has made possible the use of the most suitable types of bituminous materials. Generally this type of mineral aggregate is mixed in portable mixing plants at the roadside.

Types B and C.: The mineral aggregate of these types of pavement has during 1911 and 1912 been universally mixed in a special machine designed to heat the mineral aggregate and mix with it the bituminous material. The location of the machine depends upon local conditions. In some cases the mixing plant is located at a railroad siding at which both the broken stone and the bituminous material are available and in other cases, near the road to be constructed. In some instances large mixing plants have been installed in municipal yards. Type C is also manufactured in the form of asphalt blocks at factories. The following reference to heated aggregates in the "Am. Soc. C.E. 1912 Report" is pertinent:

Your committee recommends that in the use of a heated aggregate for the construction of a bituminous pavement, non-uniformity or excess in the heating of stone, such as usually occurs with the use of flat plates or similar crude appliances for this purpose, should be avoided.

All of the above types have been constructed with and without a seal coat of bituminous material. The best practice, however, favors the use of a seal coat.

(c) **Carpeting Methods:** In the case of macadam roads, the mode of procedure is to thoroughly clean the surface by sweeping with hand bass brooms or horse sweepers or a combination of these methods. The bituminous material, which is generally heated, is applied to the surface with the aid of pouring cans, hose attached to gravity tanks, hand-drawn gravity distributors, horse-drawn or power-driven gravity distributors and pressure distributors. After a varying interval, some kind of mineral coating is generally applied to cover the bituminous material. The construction of bituminous surfaces on bituminous concrete pavements during the construction of the latter is usually accomplished by the use of brooms, squeegees or hand-drawn gravity distributors. For a periodic application of bituminous materials all the above methods are used.

Relative Advantages and Use of Tar, Tarry Compounds, Asphalt, Bitumen, and Other Materials. Tests and Chemical Analysis of Tarry, Bituminous and Asphaltic Compounds.—Bituminous surfaces: Since 1910 there has been slowly crystallizing an objection to the use of bituminous materials on macadam roads which require from one to three weeks to "set up" to such an extent that tracking will not occur. Refined coal tars and water gas tars, combinations of asphalts and tars, and certain asphalts have given satisfaction in this respect as they have "set up" satisfactorily within 6 to 48 hours. Usually about ½ gal. per square yard has been used which has been applied either in one or two applications. In the construction of bituminous surfaces at the time of the building of macadam roads, it has been found possible to employ the same grades of asphalt as are employed in the construction of bituminous pavements by penetration methods provided large stone is used in the surface and the latter is dry and thoroughly broomed.

Bituminous Concrete Pavements: In the construction of both the mix and the seal coat of Types A, B and C, asphalts, possessing the proper physical and chemical properties, have given excellent results. Coal gas and water gas tars have been used in the construction of Type A and to a very limited extent in the construction of Types B and C. In the construction of Type A, coal tar has been used in the mix and an asphalt for a seal coat with satisfactory results. The use of high carbon tar of a certain consistency does not appear to give satisfaction as a seal coat when the traffic includes many horse-drawn vehicles. Compounds of asphalt and tar have been used in the construction of Type A and to a limited extent in the construction of Types B and C.

The amount of bituminous material used is expressed as either so many gallons per square yard of wearing surface or as a given per cent. by weight of the mix. In the various types mentioned, the amount of bituminous material used varies from 5 to 10 per cent. by weight.

Climatic Effects Causing Slipperiness of the Roadway—Remedies.—In some cases bituminous concrete pavements with seal coats of tar and certain grades of asphalt have been slippery, especially in cold weather. Many types of bituminous pavements are rendered non-slippery by the application of an additional covering of stone chips or pea gravel.

Effect on Public Health, Fish Life, or Vegetation.—The effect of using bituminous surfaces and bituminous pavements has been beneficial from the above standpoints except that the odors characteristic of certain asphaltic oils are obnoxious.

Specification of the Methods of Construction.—Detailed specifications have been drawn up covering the construction of bituminous surfaces and the various types of bituminous concrete pavements referred to above. These specifications generally cover the quality and size of the various components of the mineral aggregate, the physical and chemical properties of the bituminous material and detailed descriptions of the methods to be used in mixing and in the laying of the wearing surface. Typical detail descriptions of methods are covered by the following references:

Bituminous surfaces: Trans. Am. Soc. C.E., 1911, Vol. LXXIII., pages 44-73, and 1912, Vol. LXV., pages 548-571. Bituminous concrete pavements. Types A, B and C: Trans. Am. Soc. C.E., 1911, Vol. LXXIII., pages 99-135, and 1912, Vol. LXXV., pages 572-648. Type A: Borough of Queens, N.Y., Special Report, 1912. Type B: 1911-1912 Specifications, Washington, D.C.; 1912 Specifications, Lincoln Park, Chicago, "Good Roads," April 6, 1912. Type C: 1911 Specifications, Borough of Richmond, N.Y.; 1912 Specifications, Borough of Queens, N.Y.; 1912 Specifications, New York State Highway Commission, 1912 Specifications, City of Philadelphia.

Cost Data.—Bituminous surfaces: The average cost of constructing a bituminous surface, using 0.5 gal. per square yard with either an asphaltic or a tar product or a combination of the two, is 7 cents per square yard.

Bituminous Concrete Pavements: Besides variations dependent upon local conditions, the cost varies with the

kind and quantity of the bituminous material used, the character of the aggregate and the type of construction employed. Type A: Using an aggregate of one size crusher run stone mixed 1.5 gals. of bituminous material per square yard of 2-in. wearing surface and a flush coat of 0.75 gals. per square yard, the cost varies from 25 to 35 cents in excess of water-bound macadam. Types B and C: The cost of pavements with mineral aggregates of broken stone and sand, with or without other fine material, varies from $1 to $2.25 per square yard including the foundation course and light grading.

Cleansing and Watering.—Bituminous surfaces and bituminous concrete pavements constructed on highways outside built up districts when subjected to considerable motor car traffic are found to remain clean and practically free from dust. When subjected to excessive horse-drawn vehicle traffic in suburban or urban districts, the practice of periodical flushing at night has proved efficacious. Sprinkling with water bituminous surfaces and bituminous concrete pavements is universally condemned as tending to shorten the life of pavements and as being characteristic of uneconomical administration of street cleaning.

THE RAILWAY TIE SITUATION IN EASTERN CANADA.

By E. S. Clements,

The timber supply in Canada is by no means extraordinarily large. From the best information regarding the forests of Canada as a whole, the standing timber totals about one hundred and twenty billion cubic feet, or about fifteen thousand cubic feet per inhabitant, based on the present population. Merely as a matter of comparison, there are in the United States about five hundred billion cubic feet of standing timber, or about six thousand cubic feet per inhabitant.

So that there is only one-fourth as much available merchantable timber in Canada as in the United States, even though there is about 2½ times as much available timber per inhabitant in Canada as in the United States. It must also be considered that to a large extent the timber standing in Canada is quite small, and the amount of merchantable timber per square mile is not very great, particularly in northern forests. This explains the fact that while there are extensive forest areas in Canada, much larger than the present standing forest areas in the United States, relatively there is not the supply of timber in Canada that there is in the United States.

In the eastern portion of Canada the wooded areas along the lakes and the St. Lawrence River have been practically cut off. Lumbering operations in the territory near the lakes and the St. Lawrence River stopped some years ago. The lumber cut off was mostly white pine, but the forests have been pretty thoroughly cut up where they could be reached from the stream.

The principal lumber supplies now for Eastern Canada are the Georgian Bay district, the north shore of Lake Superior and the Ottawa River district. Mills in these sections are cutting Norway pine, spruce, hemlock, tamarack and jack pine. These are the principal woods so far as lumbering operations are concerned. They are what are called workable woods at the present time. There is, however, a large amount of hard wood, particularly in the territory which has been logged over. There is a good deal of hard wood available in the territory between Georgian Bay and the mouth of the Ottawa River, and between the Ottawa River and the lake. This timber has not been cut to any extent. The principal hard woods in this territory are birch, beech and maple. There is practically no oak.

There were 13,683,700 cross-ties purchased in Canada in 1911. The timber at present being used is cedar, spruce, tamarack, hemlock, jack pine.

There is, as stated before, hard wood available, but it is of such a character that it will rot very quickly in the track unless previously treated. The timber at present used is, of course, of a softer and weaker character, and in order to get stronger timber some of the railways have imported longleaf hard yellow pine ties from southern United States. The native woods which are used, excepting cedar, have a life averaging, say, seven years. Some of the woods, like jack pine, have less life than this. Under the present requirements of speed and load, these woods cut very quickly, and it is difficult to hold the track to gauge. This, of course, can be remedied by the use of tie plates, but the woods, excepting cedar, are very short lived and it does not pay to use the tie plates. The ties themselves rot nearly as quickly as they wear out.

A good, sound cedar tie is a most satisfactory railway tie for lighter loads. It gives a long life under light traffic conditions, and is most economical. For heavy traffic conditions and high speed, however, the cedar tie does not make a safe track, even with tie plates. As an example, the Michigan Central Railroad, on its main line, has found it absolutely necessary, as a matter of providing safe track for its high speed heavy trains, to abandon the use of cedar ties. Furthermore, for the railways located in Eastern Canada, generally speaking the cedar tie is becoming somewhat scarce and the quality available has deteriorated very materially. Consequently the Canadian railways have, in the effort to make safe tracks, imported hard pine ties from the United States, even going so far as to import yellow pine ties from Louisiana, hauling these ties 1,500 miles. It is, therefore, of great importance to note that there are hard woods available in Canada at present which, when properly treated with creosote oil, will give most satisfactory results as well as being economical.

Beech, when sound, is stronger than white oak It is very much stronger in compression across the grain than is white oak. Creosoted beech ties which have been used on the Big Four Railway in the United States for over eight years under comparatively heavy traffic show very little rail wear. The most important information as to the use of creosote in beech ties comes from France. Creosoted beech ties in that country give from twenty to thirty years' service. Creosoted beech ties have also been used on the Prussian States Railway in Germany.

The birch tie also lends itself to preservation. Its sap wood can be penetrated thoroughly. There were put in on the New York Central Railway about 1,100 birch ties treated experimentally at Shirley, Indiana, about seven years ago. These ties are at present sound, and their appearance is such that the New York Central Railway has started a campaign to get all the birch ties possible in the Adirondack territory.

Maple ties, that is the hard maple, compares favorably with beech. The sap wood can be thoroughly penetrated with creosote. Of the other woods the jack pine is the most permanent so far as creosoting is concerned. This wood being softer, it is imperative that large tie plates be used. If it is not done the ties will be rail cut long before they begin to decay.

The old English railway tracking practice was to inject from eight to ten pounds of creosote oil per cubic foot of wood. Results from this were such that Baltic fir ties (a soft

pine tie) lasted from fifteen to twenty-five years. It could not be considered good practice, on account of the loss through evaporation, to use less than eight pounds of creosote oil per cubic foot of wood. In the United States the American Creosoting Company, in creosoting some eight or nine million ties per annum, leave in these ties about eight pounds per cubic foot of wood. The actual figures used in this work are:

2¾ gallons of creosote oil for a 6" x 8" x 8' tie.
3¾ gallons of creosote oil for a 7" x 9" x 8½' tie.

Although in the treating of these ties the old English minimum of eight pounds per cubic foot is closely adhered to, these ties are treated by the Lowry process. This process is to inject in the tie an amount of oil in excess of the specified amount to be left in the tie (2¾ gallons of creosote oil for a 6" x 8" x 8' tie), this amount running up to 3¾ gallons for oak and as high as 5 to 6 gallons for pine, and sometimes even higher. The excess amount of oil is withdrawn by high vacuum, only the specified amount of oil being left in the tie. This means that the thoroughness of the penetration of the wood is as good as when twelve to fifteen pounds of oil are used by the common creosoting process, whereas actually only about eight pounds per cubic foot is left in the wood.

The most important element in creosoting wood is a thorough and deep penetration of the creosote oil. Although the old English practice for railway ties was to use from eight to ten pounds per cubic foot, in order to get better penetration present railway practice requires more than this. Ties treated by the ordinary creosoting process means the use of extra oil. By the Lowry process fully as good results are obtained, if not better, with less oil.

The most important element in creosoting timber is to have the timber properly prepared before the injection process is started. It was formerly the practice in the United States to steam timber and artificially season it. It has been proven, however, that steaming is bad practice. It is important to season the timber in air before the creosoting is started. Thoroughly air seasoned timber not only can be more thoroughly penetrated with creosote, but is stronger than green timber. To have thorough air seasoning, it is, of course, necessary to provide the ties sufficiently in advance of the time at which they are to be treated. For beech, birch, maple, jack pine, etc., the seasoning period ranges from five to eight months.

The world's highest-head water-power plant is now nearing completion at Martigny, Canton Wallis, Switzerland. The fall utilized is 5,400 feet, and the pipes conveying the water from the head of the fall to the power-house, a distance of three miles, are specially remarkable. The pressure gradually increases with the fall till the lowest part is reached, where the pipe, having to withstand 2,500 pounds per square inch, had to be made of special ingot-pressed steel. The turbines, which are of the Pelton type, have a total rating of 15,000 h.p. and it is of interest to note that, with the 5,400-foot head, only about 30 cubic feet of water per second will be necessary to develop the full 15,000 h.p. output of the station.

The Toronto Exhibition Grounds, the scene every year of the great Canadian National Exhibition, contains buildings to the value of $2,500,000. Its paved streets and street and interior lighting equipment has no rival on this continent. Over 40,000 lamps are in use during exhibition period.

COAST TO COAST.

Winnipeg, Man.—Complete reorganization of the high-pressure plant, including electrification of the whole equipment, is contemplated by the board of control. At present the whole plant is operated by gas engines supplied with gas from a producer plant in the building. The big container is falling into disrepair and the necessity of making repairs has brought to a head the proposition to change the plant so that electricity, of which the city has so much at small cost, will be the mainstay in operating the immense high-pressure pumps, while gas will be used only as a "standby." Acting on a specific recommendation from City Engineer Ruttan, the board is calling for tenders for two new pumps, which will add 20 per cent. to the pumping capacity of the present plant. It is the intention, when the new pumps are installed, to proceed with repairs to the big gas retainer, which is not in very good shape. The new pumps will supply any temporary deficiency in pumping power while the gas container is being repaired, as they will be connected with the electric power. When this is completed, it is proposed to proceed gradually to change the present equipment of the pumps so that they may be operated directly by electric power, but can be shifted to gas power on a moment's notice. It is estimated that the electrification of the plant would cost in the neighborhood of $50,000, but this amount would soon be saved by cutting off the constant cost of keeping up fires for the gas producer plant. Tenders are being called for two styles of pumps, one style to have a capacity of 360,000 Imperial gallons per minute at a pressure of 150 pounds to the square inch, while the other is to have a capacity of 180,000 gallons per minute at a pressure of 300 pounds. The efficiency of each will be about the same. Another proposal is that the gas producer plant should be cut out altogether when the plant is electrified and that the "standby" gas engines should be operated with gas from the street railway company's gas plant. A 12-inch main is laid to the high-pressure plant, and the big container would hold enough of this gas to operate the engines for any time that the high-pressure is likely to be required.

Sault Ste. Marie, Ont.—Another international question re-opening the rather vexed issue of division of international water powers is involved in an application received by the Dominion Government at Ottawa from the Michigan Superior Power Company. It came through the United States Secretary of War, with the suggestion that the two governments refer it to the joint International Waterways Commission. What is sought by the company is the privilege of damming St. Mary's River at Sault Ste. Marie in order to increase the flow of water to the works of the Michigan, Lake Superior Company at the American Soo. Compensation works to prevent the levels of Lake Superior being injuriously affected are proposed. The application is accompanied by plans and profiles of the proposed work and the compensative undertakings in connection with it. The matter doubtless will go to the Waterways Commission for full investigation, but it is evident that there will be objections not only from American standpoint, but also from navigation interests on the Canadian side. It is divined that the dam will have the effect of diverting much water which now flows through the Canadian channels, and also furnishes power to the Lake Superior Company. In many respects it is similar to the Chicago drainage canal scheme, which, it will be recalled, was vigorously combatted by the Canadian Government and ultimately rejected. A. C. Boyce, M.P., who is in Ottawa, when told of the proposal, stated that the American interests already have a larger slice of the water, the arches of the interna-

tional bridge being three-quarters on that side. "If this scheme goes through," he said, "it simply means starving the Canadian industries and navigation interests."

Ottawa, Ont.—The annual report of the surveyor-general for the last fiscal year shows that 4,550 miles were surveyed by day labor and 12,483 by contract, a total of 17,033 miles. The average cost per mile under the former system was $83.72 and under the latter $26.78. The cost aggregated $615,247. One hundred and sixty-six whole townships and eight fractional townships were completely subdivided while a partial subdivision was made of three hundred and thirty others, and a resurvey either partial or complete was made of two hundred and twenty-five others. The surveys were carried on exclusively in the western provinces. The report discusses a proposal for reciprocity among surveyors and tells of a conference on the subject. It says in part, by way of approval of the scheme: "Even if a part only of the examinations for qualifying as surveyors should be accepted throughout the empire, so that a candidate who had passed that part of the examination in any portion of the empire would be excused having to undergo it again, in order to qualify as a surveyor in another portion of the empire, a step forward would be made."

Ottawa, Ont.—The Department of Public Works has decided to leave the work of surveying Esquimalt harbor, with a view to the location of the new $3,000,000 drydock, which it is proposed to establish there, to District Engineer McLachlin, who is located at Victoria. The order and instructions, it is understood, will be forwarded to him shortly, so that there will be no delay in pushing forward the work. The engineering staff of the Public Works Department is working at the present time on the plans for the piers and harbor work at Victoria. The department is overloaded with similar work, and the preparation of the plans has been somewhat delayed. Chief Engineer Lafleur states, however, that the plans will be ready within the next month, when tenders will be called for at once.

Toronto, Ont.—The repair and renewal of small bridges and culverts during the timber or plank period of construction, has, in purely agricultural districts, been a serious drain on municipal resources, states W. A. McLean, in his annual report on highway improvements in Ontario, but the policy now being adopted of replacing these with concrete or other permanent material is one which, in the near future, promises to relieve taxpayers of this annual expenditure, and permit the outlay to be directed to more necessary road building. Some municipalities, with commendable desire to avoid public debt, are burdening themselves, and delaying progress, in order that all bridges and culverts may be built by annual levy. Where permanent material is used, construction carried on under proper supervision, and repairs provided for, there is every justification for borrowing money to build bridges of steel or concrete, extending payment over a term of twenty or thirty years. In this way those who benefit hereafter will contribute to the cost, and those who use them to-day are not unduly burdened. This does not apply (it must be emphasized) to flimsy steel trusses, weak concrete structures, wooden floors and substructures of steel legs, steel tubes and wooden backing; but only to those in which the greatest degree of permanence and strength is provided with a view to future traffic demands. The future users should not be burdened with charges for which they derive no service. Road building has, in the past, suffered much by this annual demand for culverts and bridges. A decayed bridge, or broken culvert, must of necessity be replaced or repaired, while the road, if at all safe or passable for a part of the year, can wait. It should not be forgotten that, while bridges are necessary, they are only short part of the highway; are only built because of the high way, and are an unfortunate necessity. Users of the road may pass over a bridge or culvert in ten seconds, while it may take ten minutes longer to drive over a mile of road. The writer has found many localities in which excellent bridges are being built, but in which the roads proper are in a neglected state. Good bridges should be accompanied by good roads, and every councillor may feel assured that the community which will sanction expenditure for permanent bridges, will with equal good will sanction the cost of good roads when shown a model of what well-directed expenditure will do in that regard.

St. Catharines, Ont.—Chief Engineer Weller, of the Welland Ship Canal, work on the lower section of which will begin in August, announces that the present old canal will be closed between Allanburg and Marlatt's Bridge, near Thorold, for building a new weir at the head of Lock No. 25 of the present canal, to supply the above-mentioned water. A dam will then be thrown across the old canal at Allanburg, and the old bed of the canal between the dam and Marlatt's Bridge will be utilized as a dumping ground in which to place the material removed from above water in widening the deep cut. The total length of the canal from lake to lake is 25 miles, and the difference in level between the two lakes 325½ feet, is to be overcome by seven lift-locks, each having a life of 46½ feet. The dimensions of the locks are to be 800 feet in length by 80 feet in width in the clear, and with 30 feet of water over the miter sills at extreme low stages in the lakes. The width of the canal at the bottom will be 200 feet, and for the present the canal reaches will be excavated to a depth of 25 feet only, but all stretches will be sunk to the 30-foot depth, so that the canal can be deepened at any future date by the simple process of dredging out the reaches.

Fort William, Ont.—The Dominion Government, realizing the importance of the harbors at the head of Canadian lake navigation, is doing all that can possibly be done to meet the demands of the marine trade, which during the past ten years has increased in volume over 100 per cent. Fifteen million dollars have been spent during the last ten years in harbor imrovements at this city and Port Arthur. This year alone an appropriation of two million dollars has been set aside by the Dominion Government for work in the harbor, and the contemplated improvements yet to be made will cover a period of at least five years more and will cost between fifteen and twenty million dollars. When the contemplated improvements to the harbor have been completed there will have been spent an amount approaching fifty million dollars.

Niagara Falls, Ont.—This city may soon be the scene of an engineering feat that, when completed, will go down in history as one of the greatest engineering triumphs of the times. The engineers of the Ontario Power Company are considering the construction of a tunnel under the bed of the Niagara River just above the Horseshoe Falls, the object being to provide a new water course for their powerful turbines. At the present time, the turbines are fed from two tunnels, each about eighteen feet in diameter, but the ever-increasing demand for power has taxed these channels to the utmost. These two pipes are located just under the ground surface, alongside of the street car tracks that go up to Chippewa, and experience has shown that it is not wise to duplicate this construction for future use. One is made of steel overlaid with concrete, and the other is of reinforced concrete. These are subject to atmospheric changes, and it is on this account that the peculiar location of the new tunnel has been chosen. The under waters of the Niagara River never freeze, and it has been noticed that

the temperature variation is very slight. On this account it would be an ideal spot for a power pipe, as there is a remote possibility of severe changes in temperature causing trouble to the pipes. The beginning of the new pipe will be at the dam just out from Dufferin Islands, and it will be carried almost to the brink of the Falls, then it will swing over to this side, and from here the waters will drop to the turbine house at the foot of the Falls.

Montreal, Que.—A new invention to detect the origin of noises heard at sea was tried out on the Allan liner "Victorian" on the last voyage. The ringing of bells, shouts and other noises, when heard at sea with a fog prevailing or in the darkness, are often hard to locate. The new instrument is the invention of Messrs. W. & T. G. Hodgkinson, of London. The latter gentleman sailed on the "Victorian" in order to give device a thorough testing under deep sea and ocean liner conditions. It worked well on the voyage, and he was fully satisfied with what he learned. The machinery consists of a huge drum so arranged that sound waves may reach it freely from every side. These are automatically recorded, and from this the direction from which they come is calculated. Two ships fitted with the device are at present running on the Mersey with excellent results.

Quebec, Que.—A provincial highway between Levis and Montreal, going through Sherbrooke and the Eastern Townships, is the last move decided upon by the Gouin Government. The announcement was made recently to a delegation of about one hundred representatives of all the counties on the proposed road who had assembled in the Prime Minister's office for the special purpose of presenting their views to the Cabinet. The construction of the highway was certain, explained Sir Lomer Gouin, but the government did not promise that work would be started at once, as the constructive power of the road department was already taxed to its capacity by the construction of a provincial highway on the North Shore, between Quebec and the Canadian metropolis. The proposed highway on the South Shore would, Sir Lomer added, be 250 miles long, with a link from Sherbrooke to Richmond connecting with the International road between Montreal and the United States boundary, and another link between Sherbrooke and Granby, via Magog and Waterloo. In the course of his remarks the Premier said if the government came to the conclusion that it needed more than $10,000,000 for the betterment of public roads in this province, he would be willing to borrow more money or to ask the Federal Government to increase again the provincial subsidies, which it could easily do with the enormous revenue now coming in. The Hon. J. E. Caron declared that the road department had only two skilled engineers at this time on the construction of good roads in this province, while about fifty would be required. He promised, though, that his staff would be completed and working before the end of the season.

Victoria, B.C.—Investigation of the water power resources of British Columbia, which was begun three years ago by the Commission of Conservation at Ottawa, is being continued during the present summer, Arthur V. White, of Toronto, consulting engineer on water powers for the Commission, having recently arrived in Victoria to supervise the work. Engineering parties are being placed in the field to canvass, first of all, portions of the mainland coast and the territory tributary to the Grand Trunk Pacific Railway. The party undertaking this work, according to Mr. White, will probably outfit at Hazelton. "One of the chief objects which the Commission has," stated Mr. White, "is to draw attention to the various natural resources by publishing inventories and descriptions of such resources in its various publications. The Commission has in course of preparation a report which will deal with the water powers of Western Canada. A great deal of space in this report will be devoted to the water powers of British Columbia, and, as the reports are widely distributed throughout the world, attention is directed to such a resource in a manner perhaps that would not otherwise be attained. The present work of the Commission in British Columbia, since its inception, has had the sympathy and practical support of the Provincial Government, and through the Department of Lands has received financial and other assistance, which has contributed much to facilitate the furthering of the data desired. The gathering of information in British Columbia is the most difficult work of this kind which the Commission has undertaken," said Mr. White. "No province of Canada has so many difficult problems to solve connected with the administration of its water resources, involving as it does irrigation, mining, logging, water powers and other interests. But, while this is true, the efforts made by the province through special legislation and regulations are unique, so far as Canada is concerned." Mr. White has with him on his expedition two engineers, C. J. Vick and Napier Simpson, both of Toronto, and other men will be engaged from time to time as is necessary.

PERSONAL.

Mr. THOMAS B. LEE has recently been appointed chief clerk of Robert W. Hunt & Company, Limited, in their head office at Montreal.

Mr. J. S. McLACHLAN has been appointed, by the Department of Public Works at Ottawa, a member of the corps of expert engineers to take charge of the construction of the drydock at Esquimalt, B.C.

Mr. W. A. DUFF, until recently assistant chief engineer of the Transcontinental Railway, has been appointed chief engineer of bridges of the Intercolonial Railway. Mr. Duff is a graduate in engineering of the University of Toronto.

Mr. ROBERT J. THOMAS is the newly-elected president of the American Waterworks Association. Mr. Thomas has been superintendent of waterworks at Lowell, Mass., for the past twenty-three years, and was president of the New England Waterworks Association in 1909.

ARTHUR V. WHITE, Toronto, consulting engineer on water powers for the Commission of Conservation at Ottawa, will supervise the investigation of the water power resources of British Columbia, and left recently for Victoria for that purpose. Mr. White is also consulting engineer to the International Joint Commission.

Dr. J. W. S. McCULLOUGH, chief officer of health for the Province of Ontario, will leave this week for Great Britain to obtain an expert knowledge of the treatment and disposal of sewage according to the most scientific methods known. His study will take him through all the larger cities of England, France, Germany and other countries where the same problems as those affecting Ontario are to be found.

A. N. TALBOT, of the University of Illinois, has been elected president of the American Society for Testing Materials. Professor Talbot was born in Illinois, October 21st, 1857, and graduated from the University of Illinois, civil engineering department, in 1881. He was engaged in railroad work for some years, but in 1885 returned to the university, with which he has been connected ever since. The testing of materials has been Professor Talbot's particular field for some years, and it is largely through his efforts that the materials testing laboratory at Illinois University has grown to be one of the best equipped in the country.

SIXTH ANNUAL ASSEMBLY R.A.I.C.

The sixth general annual assembly of the Royal Architectural Institute of Canada will be held at Calgary, Alberta, on September 15th and 16th, 1913. A very interesting programme is being prepared which will include matters of interest to every architect in the Dominion. The programme will be sent early in August to all the members of the R.A.I.C., and will contain all the particulars concerning the convention.

COMING MEETINGS.

UNION OF CANADIAN MUNICIPALITIES.—Thirteenth Annual Convention will be held in Saskatoon, Saskatchewan, July 15th to 17th. Secretary and Treasurer, W. D. Lightall, 305 Quebec Bank Building, Montreal, P.Q.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, J. W. H. Watts, R.C.A., Ottawa, Ontario.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Annual Meeting in Regina September 16, 17 and 18, General Secretary, Major Drum, Ottawa; Local Secretary, Dr. Murray, Regina.

AMERICAN ROAD CONGRESS—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D.C.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, Lo21 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held in Chicago, Ill., February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—176 Mansfield Avenue, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

MANITOBA BRANCH.—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack, 83 Canada Life Building, Winnipeg. Regular meetings on first Thursday of every month from November to April.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, A. B. Lambe, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

CALGARY BRANCH—Chairman, H. B. Mucklestone; Secretary-Treasurer, P. M. Sauder.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1293. Meets 2nd Thursday in each month at Club Rooms, 534 Broughton Street.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSIOCATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ALBERTA ASSOCIATION OF LAND SURVEYORS.—President, L. C. Charlesworth, Edmonton; Secretary and Registrar, R. W. Cautley, Edmonton.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, A. C. Garner, Regina; Secretary-Treasurer, H. G. Phillips, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, The Thor Iron Works, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, C. E. Bawden, Birkbeck Bld., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Hon. W. A. Charlton, M.P., Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, James Coleman; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, F. C. Mechin; Corresponding Secretary, A. W. Sime.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Edmund Burke; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Bedford McNeill; Secretary, C. McDermid, London, England, Canadian members of Council:—Prof. J. B. Porter, H. E. T. Haultain and W. N. Miller and Messrs. H. W. Claudet, S. S. Fowler, R. W. Leonard and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, J. L. Doupe; Secretary-Treasurer, W. B. Young, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 193 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, N. Vermilyea, Belleville; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. S. Dobie, Thessalon; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary-J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

QUEEN'S UNIVERSITY ENGINEERING SOCIETY.—Kingston, Ont. President, W. Dalziel; Secretary, J. C. Cameron.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

TECHNOLOGY CLUB OF LOWER CANADA.—President, F. E. Came; Secretary-Treasurer, E. B. Evans. Meets twice yearly.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President Duncan, Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary W. H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, exc June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

▲—Denotes an item regarding work advertised in *The Canadian Engineer*. +—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

PLANS AND SPECIFICATIONS ON FILE.

The following plans and specifications are on file for reference only, unless otherwise noted, at the office of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg, Man.

RAILWAYS—STEAM AND ELECTRIC.

+—Fort William, Ont.—The Canadian Pacific Railway has awarded the JOHN S. METCALF CO., LIMITED, Montreal, the contract for steel work in connection with the steel river house at Elevator "D." The contract price is $45,000.

+—Halifax, N.S.—The Dominion Government has awarded the COOK CONSTRUCTION COMPANY, Sudbury, Ont., and A. B. WHEATON, Amherst, N.S., the contract for the first section of the work on the large Intercolonial tunnel and harbor scheme. The contract is for five miles of cut-off from Rockingham, near Halifax, to the location of the proposed new docks, and will involve an enormous amount of work, as the engineering difficulties are large. The contract price is a million and a half dollars, and is in two sections. There will be a great deal of excavation necessary, and it is the intention to use all the rock and dirt on the harbor work and in the construction of the sea pier for the new docks.

+—Montreal, Que.—The Canadian Pacific Railway has awarded the DOMINION CONSTRUCTION COMPANY the contract for the construction of the double track from Sudbury to Port Arthur, the contract price being about $20,000,000 and the contract for a short line from Gliny Tay to Agincourt, the contract price being about $10,000,000.

Montreal, Que.—A report from the west states that contracts have been let by the C.P.R. for the following mileages of second track work: Revelstoke to Taft, 24 miles; Wetmore to Kamloops, 25 miles; Kamloops to Tranquille, 9 miles, and that the opening of traffic has been granted by the Board of Railway Commissioners on the second track completed between Mission Junction and Hammond, a distance of 1,829 miles.

+—Vancouver, B.C.—The Canadian Pacific Railway has awarded the CANADIAN NORTH-WEST STEEL COMPANY, Vancouver, the contract for supplying the steel for the Burrard Street viaduct.

LIGHT, HEAT AND POWER.

Calgary, Alta.—Tenders will be received up till the 16th of July, 1913, for supplying paper insulated light and power underground cable. Specifications may be obtained from J. M. Miller, city clerk.

▲—Carlyle, Sask.—Tenders will be received up till the 1st of August, 1913, for the supplying power and lighting equipment. Plans and specifications may be obtained from the consulting engineers at Winnipeg and Calgary. F. J. Stent, secretary-treasurer.

Hamilton, Ont.—Mr. E. I. Sifton, Hydro Engineer, stated that the tie-up in the power system recently was due to more defective insulators discovered in the territory not before inspected by the dozen men the commission has camping along the right-of-way looking for such trouble. The Hamilton controllers had a special meeting and on being told that the difficulty was being experienced near the source of supply, decided to have some steps taken at once to erect an auxiliary plant.

+—Medicine Hat, Alta.—The city has awarded the INTERNATIONAL SUPPLY CO. the contract for drilling natural gas wells in the municipality. Nine new wells will will be drilled, which will be located in various parts of the city by City Engineer Grimmer. The price involved is $75,000.

Medicine Hat, Alta.—The city council has authorized City Engineer Grimmer to place an order for six 500 K.W. transformers. In speaking of this feature of the equipment Mr. Grimmer said that the matter had been carefully gone into with Consulting Engineer Lea. While a voltage of 6,600 was considered large enough for cities of from 25,000 to 40,000, the wonderful growth of Medicine Hat and its future convinced the expert that double that voltage would be eventually required. Accordingly it was decided to install a total of 13,000 volts.

Toronto, Ont.—Acting on the advice of Mr. H. H. Couzens, general manager of the Toronto Hydro-Electric System, the Hydro Commission has decided to provide a steam reserve for the purpose of making impossible such breakdowns in the service as have been experienced recently. Mr. Couzens estimates the cost of such a plant to be about $1,000,000, and states that it should be located near the waterfront.

Winnipeg, Man.—Tenders will be received up till 9th of August, 1913, for the manufacture, delivery, and erection of one 1,000 k.w. motor generator. Plans and specifications may be obtained from the Board of Control. M. Peterson, secretary.

GARBAGE, SEWAGE AND WATER.

+—Calgary, Alta.—On the ground that the firm offers the most superior pipe, the city council, acting on the recommendation of Commissioner A. G. Graves, supported by Water Engineer A. Ellison Fawkes and City Engineer G. W. Craig, has awarded the contract to the GENERAL SUPPLIES, LIMITED, for putting the new high pressure main under the Elbow River. The company offered the 24-inch pipe for this line at $5,244, and it was not the lowest tender. Other tenders included the following: Metals, Limited, $3,750; Broley and Martin, $4,700; Gorman, Clancy and Grindley, $5,129; the Canada Iron Corporation, $5,563.

▲—Carlyle, Sask.—Tenders will be received up till the 1st of August, 1913, for construction of waterworks. Plans and specifications may be obtained from the consulting engineers at Winnipeg and Calgary. F. J. Stent, secretary-treasurer.

Edmonton, Alta.—With capital to the extent of $65,000 invested in the undertaking, a present working force of 125 men, which will be increased within the next month to 225, and five miles of narrow-gauge track connecting their plant, at the corner of Columbia Avenue and Thirteenth Street, with the extreme northern and eastern portions of the city, Messrs. Henry C. and John R. Ulen, of Chicago, commenced work on July 1st, of the sewage contracts from the city involving an aggregate amount of nearly a million and a half dollars.

Edmonton, Alta.—The City Commissioners have received the following tenders for sewers: Alex. Benson, unit prices; C. L. de Vall, $73,918; A. J. McGarry and Hulbert and Wilson, unit prices. For water mains the bids were as follows: C. L. de Vall, G. Stranger, Phillip Agrios, W. J. Graham, all unit prices. These were referred to City Engineer for report.

Esquimalt, B.C.—The ratepayers have authorized the council to raise the sum of $40,000 on the credit of the municipality for the installation of a sewerage system.

Montreal, Que.—City Engineer Janin has recommended that the following tenders be accepted: In Mount Royal Ward the recommendation is that the first section of the main sewer be given to the Harris Construction Co., price $140,432, and the second section to Henault and Heffernan, price $156,437. In Notre Dame de Grace the tenders recommended for main sewer are: F. O. Sullivan, fourth section, $78,940, and Zenon Corbeau, fifth section, $109,857. Among other tenders recommended were the following: Alice Street, Cote St. Lawrence Road to 29th Avenue, A. F. Dillon, $32,350; Rosemount Boulevard, St. Michael to Desjardins, city of Montreal, $22,434; Mountain Street, Sherbrooke Street to north, Henault and Heffernan, $9,571; Contrecoeur Street, from river to Sherbrooke Street, Salvator Ricci and Co., $15,247. The same firm's tender is also recommended for part of Berri Street, $16,857. Tenders by Henri Bertrand, ranging from $740 up to $3,324, are also recommended for work on streets in the north and east. Tenders of Gilbert Paye and Company are recommended for part of Rosemount Boulevard, Delorimier to Cabot, $6,545; Bordeaux, Descarrieres to Rosemount Boulevard, $4,493, and lesser contracts.

Montreal, Que.—A report made to the Board of Control on sewage disposal in Notre Dame de Grace quotes $5,000 as the outside cost for the establishment of a system. R. G. Lea, civil engineer, who made the report, suggests, however, that the scheme should be allowed to stand over till the autumn, as sewage disposal is receiving attention from a parliamentary committee, and is to be discussed at an American convention which Mr. Lea will attend.

Montreal, Que.—The Board of Control has at last received from the Montreal Water and Power Company a definite offer as to what terms, the company will sell its entire plant to the city. The offer may serve as a basis upon which the Board of Control and the City Council can reach an amicable settlement. The report states that it is the company's desire that the buying out of its plant be taken up in an amicable spirit, and that the directors are anxious to make a fair business-like arrangement.

+—Port Coquitlam, B.C.—MESSRS. MOON & SILVERTON, Vancouver, have been awarded the contract for installing a system of trunk water mains. The contract price is $23,579. The pipe they will supply is manufactured by Stewart and Lord, of Birmingham.

Regina, Sask.—Realizing that although the pumps at the power house can furnish the domestic water supply with a struggle, it is rather risky to trust to them alone in case of fire, the waterworks department has secured two turbine pumps with a combined capacity of 1,440,000 gallons per day at ordinary pressure. For fire use they will be run tandem, that is, one raising the stream of water to ordinary pressure and the other doubling that pressure. In the meantime the plans are ready for replacing one of the older power units with the new 5,000,000 gallon pump.

Vancouver, B.C.—The report of City Engineer Fellowes recommending the laying of two-inch water pipes on First Avenue east of Renfrew Street and on Twenty-third Avenue from Kaslo Street to a point 250 feet west has been adopted. Tenders for the supply of 3,750 lineal feet of 18-inch cast iron flexible pipe for the Point Grey partnership pipe for the False Creek submerged main will be called for.

▲—Victoria, B.C.—Tenders will be received up till the 31st of July, 1913, for the fabrication and laying of about 10¼ miles of 36-in. riveted steel pipe and appurtenances on the line of the Sooke Water Supply. Plans and specifications may be obtained from C. H. Rust, Water Commissioner.

▲—Victoria, B.C.—Tenders will be received up till the 31st of July, 1913, for the laying of about 27½ miles of reinforced concrete pipe and appurtenances on the line of the Sooke Water Supply gravity conduit. Plans and specifications may be obtained from the Sooke Water Supply office, and C. H. Rust. Water Commissioner.

Weyburn, Sask.—Tenders will be received up till the 12th of July, 1913, for the trenching, pipe laying and backfilling ten-inch wooden pipe line. Plans and specifications may be obtained from J. G. Sullivan, Winnipeg, J. G. Martin, Moose Jaw, and T. Martin, Division Engineer of the Canadian Pacific Railway, Moose Jaw, Sask.

BUILDINGS AND INDUSTRIAL WORKS.

+—Charlottetown, P.E.I.—The JOHN S. METCALF CO., LIMITED, Montreal, have been awarded the contract for the rebuilding of the Roman Catholic Cathedral. The contract price is $150,000.

▲—Cochrane, Ont.—Tenders will be received up till the 22nd of July, 1913, for the erection of an ice house, store house, freight house, and two tool houses. Plans and specifications may be obtained from Mr. Gordan Grant, Ottawa, and Mr. T. S. Armstrong, Cochrane, and the Commissioners of the Transcontinental Railway. P. E. Ryan, secretary.

+—Edmonton, Alta.—The Grand Trunk Pacific Railway has awarded the ALBERTA ORNAMENTAL IRON COMPANY, Redcliffe, the contract for the ornamental iron and bronze work on the Chateau McDonald.

Edmonton, Alta.—The City Commissioners have received the following tenders for fire halls: Congdon and Oliver, $17,260 and $17,189; Nesbitt and Miller, $26,697, $11,942, $14,493, $14,043, for halls Nos. 7, 8, 9, and 10 respectively; Dunlop Johnson Construction Company, hall No. 8, $12,700 and $12,890; No. 9, $13,232 and $13,365; No. 7, $26,892 and $27,440; No. 10, $13,187 and $13,300. Jones, Lyttle Company, $27,300, $12,900, $13,300 and $13,200. For plumbing and heating on these fire halls the following were received: Edmonton Metal Works, Nos. 8, 9, and 10, $2,273; McKnight and Frost, $3,984, $1,792, $1,774 and $1,787 for each of the four halls; Ross Brothers, $1,835, $4,120, and $1,835. The city construction department also put in a bid. These offers were referred to the city architect for tabulation and report.

+—Fort William, Ont.—Thte Steel Company of Canada, Limited, has awarded MESSRS. PRACK & PERRINE the contract for the company's plant. The contract price is $300,000.

Fort William, Ont.—The building permits for June of this year amounted to $431,735. For the same month last year they amounted to $232,070. This is an increase of $199,665.

Beaconsfield Station Road, Beaconsfield, Quebec, before Tarvia Modern Pavement was laid.

Beaconsfield Station Road, after Tarvia Modern Pavement was laid.

Before and After the Use of

Tarvia

Preserves Roads Prevents Dust~

HERE is a road which could not stand the traffic when it only had the natural binder. The addition of Tarvia as a binder when the road was resurfaced made a wonderful difference and the roadway became of adequate toughness to resist traffic of every kind.

Tarvia is a dense, tough, plastic preparation of coal tar.

In this road, the Tarvia was applied during reconstruction. In each layer of stone Tarvia was poured to fill all the voids and form a tough, plastic matrix in which the stone was firmly set.

The road is thus bonded with the Tarvia throughout its whole depth; it will keep its contour for many years, for it is a solid mass of tough "tarvia-concrete." The screenings on the surface will, of course, suffer somewhat from the continual friction of traffic and will need renewal at rare intervals. In such renewal operations "Tarvia B," a light grade of Tarvia will, undoubtedly, be used.

The road costs a little more than ordinary macadam to construct, but it will also cost a great deal less than ordinary macadam to maintain. The Tarvia surface will stay smooth, waterproof and dustless for years with trifling attention and repairs.

There are three kinds of Tarvia—"Tarvia X," very heavy and dense for road construction where the voids are large; "Tarvia A," a lighter grade for the smaller voids which occur in surface operations; "Tarvia B," applied cold for dust suppression and surface maintenance.

Booklets free on request.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Hantsport, N.S.—Tenders will be received up till the 17th of July, 1913, for the construction of an extension to a wharf. Plans and specifications may be obtained from the District Engineers at Halifax and Antigonish and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Kemptville, Ont.—Tenders will be received up till the 21st of July, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy-Minister.

Lakefield, Ont.—Tenders will be received up till the 21st of July, 1913, for the construction of a public building. Plans and specifications may be obtained from Thos. Hastings, Toronto, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Lakefield, Ont.—Tenders will be received up till the 21st of July, 1913, for the construction of a public building. Plans and specifications may be obtained from Mr. Thos. Hastings, Toronto, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Lloydminster, Sask.—Tenders will be received up till the 25th of July, 1913 for the interior fittings for post-office, customs and inland revenue office. Plans and specifications may be obtained from Mr. W. T. Mollard, Regina, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—**Medicine Hat, Alta.**—MESSRS. SACKRIDER AND TURNER have been awarded the contract for the erection of the addition to the Elm Street Public school, the price quoted being $59,948. Smith Brothers and Wilson, of Lethbridge, tender was only $2 higher, while Hotson, Leade, and Goode, Horton and Willets, Lussier Construction Company, Fisher and Martin, of Calgary, also put in tenders. The contract for the heating and ventilating was let to MARSH & SCOTT at $13,057.80, and they will also connect up with the ventilating system of the old building for $3,927. Sackrider & Turner undertook to do the plumbing and fitting for $2,500.

Medicine Hat, Alta.—The Great West Iron, Wood and Chemical Co. will construct a car wheel and underframe works in this city. The cost is estimated to be $1,000,000.

+—**Montreal, Que.**—The ATLAS CONSTRUCTION COMPANY have been awarded the contract for the Timmins Building. MR. E. GROSS has been awarded the contract for the painting and glazing.

Moose Jaw, Sask.—The Royal Bank will erect a building in this city. The estimated cost is $70,000.

New Westminster, B.C.—The Provincial Government has sanctioned the construction of the harbor works on the Fraser River. Work will commence at once.

North Bay, Ont.—Work has been started on the erection of the additions to the shops of the C.P.R. here, and among the buildings to be put up will be an erecting shop, with accommodation for the repair of ten locomotives, a car construction and repair shop, and an additional machine shop.

▲—**Ottawa, Ont.**—Tenders will be received up till the 29th of July, 1913, for supplying a steel pontoon gate lifter for Trent Canal. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. J. K. Jones, secretary.

Ottawa, Ont.—A cheque for $75,000 deposited by the Halifax Dredging Company in connection with the contract for building the Prince Edward Island terminal for the I.C.R. car ferry, has been forfeited to the government for failure to carry out the work. New tenders are being received.

Pitt River, B.C.—Tenders will be received up till the 23rd of July, 1913, for dredging required at Pitt River. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Prince Albert, Sask.—The National Iron and Steel corporation will locate a plant in this city which will employ 5,000 men inside of four years. The company will use 4,200 horsepower from the new city power plant now in course of erection at Lacolle Falls.

Redcliffe, Alta.—The H. Munderloh Company of Montreal will erect a plant in this city for the manufacture of sheet glass. The plant will cost $200,000.

+—**Regina, Sask.**—MR. CHARLES D. OLIVER, the Canadian representative of the System M has been awarded the contract for the steel work on the new Sherwood store. In this system, the columns, girders and beams used in the buildings are composed of structural steel used in tension only, the strength in compression being developed by the concrete surrounding the steel work. Practically, the buildings erected on this plan differ from the usual run of steel frame buildings in that they are steel reinforced with concrete rather than concrete reinforced with steel.

Regina, Sask.—The Farmer's Co-operative Company will erect a fruit storage warehouse in this city. The estimated cost is $20,000.

Saskatoon, Sask.—Tenders will be received up till the 12th of July, 1913, for the cleaning and painting of steel work of the traffic bridge over the South Saskatchewan River. Plans and specifications may be obtained from the Board of Highway Commissioners; A. J. McPherson, chairman.

+—**Toledo, Ohio.**—The MacARTHUR CONCRETE PILE AND FOUNDATION COMPANY, New York City, has been awarded the contract for the concrete piles required in the foundation of the new Ash Street bridge.

Toronto, Ont.—Tenders will be received up till the 15th of July, 1913, for the erection of court house and registry office at Haileybury; a court house at Fort Frances, poultry building at the Ontario Agricultural College, Guelph; dormitory building for the Ontario Institution of the Blind, Brantford, and a dormitory building for the Ontario Institute for the Deaf and Dumb, Belleville. Plans and specifications may be obtained from the Department of Public Works, Toronto. H. F. McNaughton, secretary.

Toronto, Ont.—The new viaduct plans for Toronto mean the abandonment of the million-dollar dock project of the Richelieu and Ontario Navigation Company. This dock was to have been built out as far as the present Windmill line, but the five-million dollars' publicly-owned dock plans of the harbor involve the expropriation of the property now held by the R. and O. line.

+—**Toronto, Ont.**—The Dominion Abattoir Company has awarded the SMART-TURNER MACHINE CO., LIMITED, Hamilton, the contract for supplying a triplex power pump.

▲—**Valleyfield, Que.**—Tenders will be received up till the 18th of July, 1913, for the construction of a protection for the Government dam. Plans and specifications may be obtained from Chief Engineer, Ottawa, Supt. Engineer, Quebec, Canals, Montreal and the Department of Railways and Canals, Ottawa. L. K. Jones, secretary.

+—**Victoria, B.C.**—The School Board has awarded MESSRS. KNOTT & JONES the contract for the erection of the Esquimalt school. The contract price is $64,000.

Welland, Ont.—The building permits for the month of June amounted to $34,976. For the same month last year they amounted to $19,313. This is an increase of $15,663. D. T. Black, town engineer.

▲—**Windsor, Ont.**—Tenders will be received up till the 29th of July, 1913, for the construction of an incinerator. Plans and specifications may be obtained from M. E. Brian, city engineer.

+—**Winnipeg, Man.**—The Bank of Hamilton has awarded MESSRS. JOHN GUNN & SONS the contract for the erection of a new building at Minnedosa.

+—**Winnipeg, Man.**—Mr. W. B. Chambers has awarded MESSRS. SIMMONS BROTHERS the contract for an apartment block. The contract price is $55,000.

+—**Winnipeg, Man.**—MR. JAS. McDERMID has been awarded the contract for the new Pantages theatre building. It will be of French renaissance style, and the contract price is $180,000.

+—**Winnipeg, Man.**—The ALBERTA ORNAMENTAL IRON COMPANY have been awarded the contract for the ornamental iron and bronze work on the new Confederation Life Building.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—The city paving plant is giving a splendid demonstration these days of the city doing its own paving. The plant is now laying 2,000 yards of paving a day, and is putting down a better quality of pavement than any it has ever been possible to obtain by contract. The saving being effected amounts to about 50 cents a yard, or $1,000 a

MANNESMANN TUBE COMPANY, LIMITED

51 VICTORIA SQUARE, MONTREAL

day, to the city. Under the supervision of Commissioner Samis, the repairs to pavement poorly laid by contractors in the past are being made with good expedition, and the Mineral Rubber Company is completing the work left undone on its last year's contract.

Halifax, N.S.—Tenders will be received up till the 19th of July, 1913. for the construction of bridges and culverts in the County of Guysboro. Plans and specifications may be obtained from E. H. Armstrong, Commissioner of Public Works and Mines, Halifax, N.S.

+—Montreal, Que.—Tenders are being considered by the Board of Control for asphalt plants. The lowest was that of the BITULITHIC PAVING CO., LIMITED, namely, $31,950 for fixed plant. As this exceeded the amount voted for the purpose, the council will be asked to vote the necessary extra amount in order that this tender may be accepted. For a movable plant, the tender of F. D. CUMNER & COMPANY, for $16,500, was recommended.

Port Arthur, Ont.—Tenders will be received up till the 14th of July for the grading, constructing curbs and laying Rocmac roads. Plans and specifications may be obtained from the corporation office, J. J. Hackney, Commissioner of Utilities.

▲—Saskatoon, Sask.—Tenders will be received up till the 15th of July, 1913, for the construction of a concrete bridge over the South Saskatchewan River. Plans and specifications may be obtained from the Board of Highway Commissioners. A. J. McPherson, chairman.

▲—Saskatoon, Sask.—Tenders will be received up till the 21st of July, 1913, for supplying boulevard posts. Specifications may be obtained from Mr. E. Harrison, City Electrical Engineer, and the Board of Commissioners. F. E. Harrison, chairman.

Saskatoon, Sask.—Tentative plans for the proposed concrete bridge which will span the river at 25th Street, have been submitted to the city commissioners, and the general scheme has been approved by them on behalf of the city. The drawings are not complete as far as details are concerned, but they are sufficient to provide all the information necessary for the contractors who will tender for the work. After July 15th, by which time the tenders must be all in, the provincial government will issue new and complete plans giving all the information required to carry on the work. The city will pay one-third and the government two-thirds of the cost which was formerly estimated at $300,000. At the last election the ratepayers authorized an issue of $100,000 debentures to cover the city's share of the expense, but owing to the money situation in London these have not been disposed of.

+—Seattle, Wash.—The Board of Public Works has awarded MESSRS. NETTLETON-BRUCE-FACHBACK, Seattle, the contract for a dam at Cedar River. The contract price is $687,110.

+—Selma, Ala.—The DOLARWAY PAVING COMPANY have been awarded the contract for the laying of 20,000 square yards of pavements. The contract price is not given.

+—St. John, N.B.—The Board of Commissioners have awarded the WARREN BITULITHIC COMPANY the contract for laying its pavement on four streets at $1.88 per yard. The total contract price is $29,916.

+—St. John, N.B.—The Board of Commissioners have awarded the following paving contracts:—For paving Union Street, the following tenders were received:—Messrs. George and L. Corey, granite block, $6,937.50; vitrified brick, $7,500.00; Granite Street Paving and Construction Co., granite block, $4,755.50; vitrified brick, $4,859; B. Mooney and Sons, granite block, $4,778.60; vitrified brick, $4,850.60; A. R. C. CLARK, granite block, $4,474; vitrified brick, $4,564. The latter company were awarded the contract. For paving Germain Street, the following tenders were received:—A. R. C. Clark, granite block, $4,161.50; vitrified brick, $4,161.50; George and Corey, granite block, $6,315.75; vitrified brick $6,335.75; ERNEST RYERSE, granite block, $3,716.50; vitrified brick, $3,552.50. The latter company were awarded the contract.

+—Vancouver, B.C.—The Canadian Northern Railway has awarded the CANADIAN NORTH-WEST STEEL COMPANY the contracts for the construction of ten bridges. They will be of the heavy plate deck girder span type.

CURRENT NEWS.

Lethbridge, Alta.—Immigration Agent A. E. Humphries has been requested by Commissioner J. Bruce Walker, of the immigration department, to open a hundred pound sample of Lethbridge coal for transhipment to Berlin, Germany, where it is to undergo a test by a large industrial concern who believe that the semi-bituminous coal of Southern Alberta is peculiarly fitted to their requirements. Commissioner Walker says in his letter to Mr. Humphries: "The department is anxious to ship this sample to Berlin, where it is proposed that it shall undergo a certain test and if satisfactory the coal may form the nucleus of an organization of considerable industries using coal of a special character."

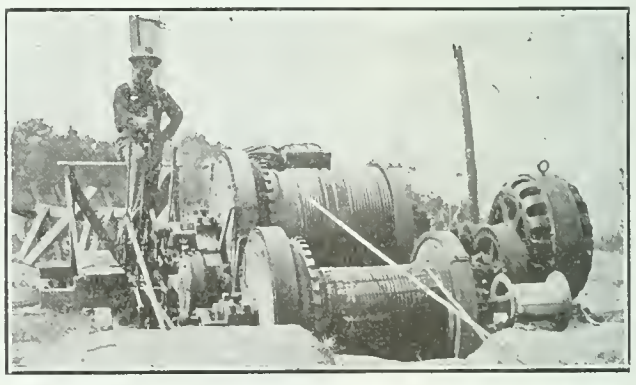
Sault Ste. Marie, Mich.—For the second time this year all previous records for one month's commerce through the American and Canadian canals at Sault Ste. Marie is broken by the showing made in June, when freight carried through the waterways aggregated 12,113,613 tons. These figures given in the statistical report compiled by Superintendent L. C. Sabin under direction of Lieutenant-Colonel Mason M. Patrick, district engineer, compare with a freight movement of 11,376,195 tons in May this year, and with 10,747,159 tons in June, 1912. The amount is nearly as great as the freight movement for the entire season of 1894 when the total traffic through the canals was 13,195,860 tons.

Saskatoon, Sask.—A notable convention to be held here July 15th, 16th, and 17th, will be that of the Union of Canadian Municipalities. This will bring more than 300 mayors, aldermen and commissioners, controllers and other civic officials to Saskatoon, to confer upon matters of civic moment. Every possible arrangement is being made for the entertainment of the visitors, who will be given opportunity to see the modern lines of Saskatoon's civic administration, and who will be able to look over the city's public utilities. The following subjects will be discussed at the convention: Watering the Stock of Public Utility Corporations, Providing for the Welfare of the Working Population, Inter-provincial Highways, Treatment of Garbage versus Incineration, Wants of Rural Municipalities, Improved Systems of Water Filtration and Purification, Under-representation of Cities, Town Planning, Experiences of a General City Manager, Improvement and Preservation of the Great Inland Waterways.

MOTOR-DRIVEN HOIST USED ON A SCRAPER.

In order to remove the worthless soil above a valuable deposit of clay, the Twin City Brick Co., St. Paul, Minn., uses a drag bucket operated by a motor-driven hoist.

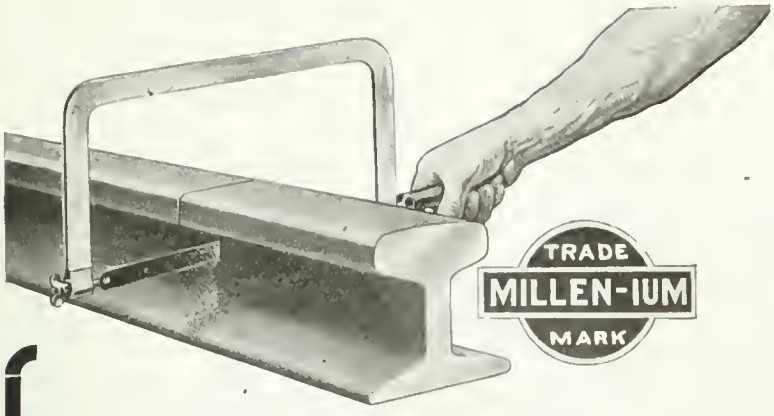
The clay deposit forms a bluff above the plant and the bucket is dragged over the surface, removing the soil on its down trip and returning empty. The bucket handles about 300 cubic feet of soil and makes a trip every two minutes.



Showing Hoist Driven by Induction Motor.

The hoist is a double drum American, and is driven by a 75 horse-power Westinghouse induction motor.

The use of electric-drive is especially desirable for such an operation because it eliminates the hauling of fuel and water, enables one man to handle the entire machine, and involves no delays while steaming up. The hoist, being without a boiler, is also much easier to re-locate.



MILLEN-IUM

HIGH SPEED

Hack Saw Blades

are certainly making good with exacting users throughout the country, as we were sure they would.

Our confidence in these British blades is based on thorough tests in our own warehouse, extending over several months, cutting Shelby Tubes in lengths to suit our customers. They cut cleaner and faster, and stand up to this difficult work better, than any other blades we have ever used.

Our confidence in their high quality is expressed by putting them out under our own name and the "MILLEN-IUM" Trade Mark.

Millen-ium High Speed Hack Saw Blades are not cheap in first cost—but you'll get the most service out of them per dollar paid.

Write us for a Sample Millen-ium Blade for either hand or machine work, stating the kind of material you wish to cut, and we'll send it promptly without charge.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction of the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

19612—June 17—Approving location station grounds of G.T.P. Ry. through Charles Indian Reserve No. 1, mileage 317, Coast Dist., Rge. 5, British Columbia.

19613—June 17—Approving proposed station site and station of G.T.P. Branch Lines, at Totzke, in Sec. 20-38-26, W. 2 M, on Prince Albert Branch, Saskatchewan.

19614—June 18—Authorizing C.P.R. to construct bridge No. 312, near Elmsley Station, Havelock Sub. Div., Ont. Div., Ontario.

19615—June 18—Authorizing C.P.R. to revise grade of present grade crossing on Sims St., Webbwood Sub. Div., Lake Superior Div., Tp. Hallam, Dist. Algoma, Ontario.

19616—June 18—Approving plan "D" showing details of substructure of bridge No. 265, at mileage 46.80 on 13th Dist., Hamilton Division, G.T.R., Ontario.

19617—June 18—Authorizing Corporation Tp. Brantford, Ont., to construct, at its own expense, a public highway, known as "Humberstone Ave.," across Brantford & Hamilton Electric Ry. Co. in Tp. Brantford.

19618—June 11—Cancelling approval of station (G.T.P. Ry.) at Empire Ave., Lot 8, Con. 2, Tp. Neebing, mileage 0.7, Lake Superior Branch, as approved under Order No. 19377, dated May 26/13.

19619—June 17—Authorizing Hamilton St. Ry. Co. to cross, subject to conditions contained in by-law No. 1430, at rail level, the switch track of T.H. & B. Ry. at Burlington (Gilkinson) St., city of Hamilton, Ont., subject to and upon certain conditions.

19620—June 12—Approving location C.P.R. Suffield-Blackie Branch, from a point in Sec. 9—13—17, W. 4 M., in westerly direction to a point in Sec. 13-19-27, W. 4 M., mileage 58.29, to mileage 149.9 of said branch, in Province of Alberta; and authorizing construction of said branch across eighty-nine (89) highways, mileages 58.29 to 149.9, diversion of certain highways and closing up portions so diverted.

19621—June 19—Authorizing C.P.R. to construct bridge No. 65.4, near Addington Station, Havelock Subdivision, Ont. Div., Ontario.

19622—June 19—Recommending to the Governor in Council for sanction the Indenture of Lease entered into between C.L.O. & W. Ry. (C.P.R.) and the C.P.R.

19623—June 19—Authorizing C.L.O. & W.Ry. (C.P.R.) to construct across road allowance between Lot 35, Con. 1, Tp. Hamilton and Co. Northumberland, and Lot 1, Con. 1, Tp. Hope and Co. Durham, Ont., at mileage 124.83 from Glen Tay; and rescinding Order No. 17163, dated August 1st, 1912, in so far as it authorizes said crossing.

19624—June 18—Directing that G.T.R. trains, operated over crossing of highway known as Wellington St. Crossing, just north of Aurora Station, Ont., be limited to a speed not exceeding ten (10) miles an hour; that all switching movements over said crossing be flagged.

19625—June 19—Extending, until July 17th, 1913, time within which G.T.R. install bell at crossing of Main Street, village of Thorndale, Ontario, required under Order No. 18887, dated March 17th, 1913.

19626—June 19—Authorizing G.T.R. to construct siding into premises of Galt Stove & Furnace Co., Ltd., town of Galt, Ontario; siding to be constructed within three months from date of this Order.

19627—June 18—Approving location G.T.P. Branch Lines Co.'s station on its Battleford Branch, at Lett, in Sec. 27-37-16, W. 3 M., Saskatchewan.

19628—June 18—Approving (1) revised location G.T.P. Branch Lines Co., Biggar-Calgary Branch, in W. ½ Sec. 29-33-18, W. 3 M., Dist. of Saskatoon, Sask.; and (2) approving location of said company's station in W. ½ of Sec. 29-33-18, W. 3 M., Saskatchewan.

19629—June 17—Authorizing C.N.Q.R. to construct across public road in village of St. Eustache, Parish of St. Eustache, Co. of Two Mountains, Quebec; and reserving question of protection to be provided at said crossing.

19630—June 17—Authorizing C.N.R. to construct spur for Manitoba Gypsum Co., Ltd., through Lot 20, R.L. 41, and Lot 4, R.L. 42, St. James, in city of Winnipeg, Man., subject to and upon certain conditions; spur to be completed within three months from date of this Order.

19631—June 18—Authorizing C.N.R. to divert River Road, near Victoria Bridge, Calgary, Alta., and to take necessary land for purpose of carrying out proposed diversion; company to maintain said road diversion for a period of one year from date of this Order.

19632—June 19—Extending, until Sept. 1st, 1913, time within which C.N.O.R. install gates at crossing of Bridge Street, village of Yarker, Tp. Camden, Co. Addington, Ont., as required under Order No. 17739, dated October 4th, 1912.

19633—June 18—Authorizing G. R. Duncan, Fort William, Ont., to construct siding from his property, being a part of S.W. ¼ of Sec. 52, in Tp. McIntyre, across Waterloo St., Port Arthur, to right of way of C.N.R., C.N.R. to build remainder of siding.

19634—June 19—Authorizing N.Y. Central & Hudson River R.R. Co. to construct spur into property of Howard Smith Paper Mills, Ltd., on Lot 556, on official plan and book of reference of town of Beauharnois, Quebec; spur to be constructed within three months from date of this Order.

19635—June 19—Authorizing C.P.R. to construct road diversion in Secs. 15 and 22-23-18, W. 5 M., at mileage 36 from Golden, B.C. After such diversion company may close portion of present road allowance to be diverted as aforesaid, within limits of its right-of-way.

19636—June 20—Authorizing C.P.R. to construct spur for Canadian Lumber Yards, Ltd., Winnipeg, Man., from a point on existing spur in lane in Block 72, City of Moose Jaw, Sask., thence across said land and across Subdivision Lots 23 to 38; spur to be completed within three months from date of this order.

19637—June 20—Authorizing C.P.R. to open for traffic portion of Edmonton Subdivision of its line, from Strathcona, B.C., to a point south of Jasper Ave., Edmonton, including high level bridge over North Saskatchewan River; provided in operation of said bridge speed of trains be limited to rate not exceeding 12 miles an hour.

19638—June 20—Directing that crossing of Rue Plinguet by C. P.R., in City of St. Boniface, Man., be protected by watchman between 7 a.m. and 7 p.m.

19639—June 19—Approving location C.P.R. additional track (double track), from Islington, Tp. Etobicoke, mileage 10, to Guelph Jct., Tp. Nassagaweya, at mileage 39.1, London Subdiv., Ont. Div.

19640—June 19—Authorizing C.P.R. to construct road diversion in Sec. 28-23-18, W. 5 M., at mileage 33.47 from Golden, B.C. After such diversion company may close portion of present road allowance within limits of its right-of-way.

19641—June 19—Authorizing C.P.R. to construct road diversions at Sec. 6-24-18, W. 5 M., mileage 31.2 from Golden, B.C., and also at mileage 35.6 in Secs. 15 and 22, Tp. 23, R. 18, W. 5 M.

19642—June 20—Authorizing G.T.R. to construct siding for Samuel McCord, Toronto, Ontario; siding to be completed within three months from date of this order.

19643—June 16—Approving location Ten (10) G.T.P. Branch Lines Co. stations in District of Cariboo, B.C.

19644—June 19—Approving location Kettle Valley Rly. Co., from mileages 0 to 20, Hydraulic Summit to Penticton, B.C.

19645—June 18—Authorizing Algoma Eastern Rly. Co., subject to conditions contained in Order-in-Council, dated June 10th, 1913, to construct dock at Goat Island, near Town of Little Current, Manitoulin Island, District Manitoulin, Ontario.

19646—May 16—Authorizing C.P.R. to operate interlocking plant at Batiscan River Bridge, on Quebec Subdivision of its railway, at mileage 102.5, subject to and upon condition that when a distant semaphore is at "Caution," all trains must stop at that semaphore until it is cleared, as well as at the home semaphore.

19647—June 14—Extending, until Aug. 15th, 1913, time within which C.P.R. install electric bell at crossing of highway at Glen Major flag-station, Ont., by Toronto-Montreal Line of C.P.R., and required to be installed by Order No. 18872, dated March 15, 1913.

19648—June 20—Amending Order No. 19571, dated June 12th, 1913, by striking out word "Carmen" where it occurs in said order, and substituting therefor the word "Carman."

19649—June 18—Authorizing C.P.R. to construct road diversion in Sec. 4-20-19, W. 3 M., and construct its Swift Current Northwesterly Branch, by means of a grade crossing, across said road diversion, at mileage 40.84 (from Swift Current).

19650—June 20—Directing that, within 90 days from date of this order, C.P.R. install improved type of automatic electric bell at crossing of March Road, 6.4 miles west of Ottawa, Ont., 20 per cent. of cost of installing bell to be paid out of "The Railway Grade-Crossing Fund," and remainder by C.P.R.

19651—June 20—Approving (1) revised location C.L.O. & W. Ry. (C.P.R.) from mileage 75.45 to mileage 77.45 from Glen Tay; and (2) location of said company's line from mileage 77.75 in westerly direction to mileage 79.5, a point on western boundary of E. ½ Lot 31, Con. 1, Tp. Sidney, Co. Hastings, Ontario.

19652—June 20—Extending, until July 31st, 1913, time within which C.P.R. install gates at crossing of Lake Shore Road by G.T.R. and C.P.R., at Vaudreuil, Que., required to be erected under Order No. 19308, dated May 16th, 1913.

19653—June 18—Amending Order No. 18419 to provide that crossing over 17th Ave. East, Calgary, Alta., is authorized upon following conditions: (a) Approach on east side be reduced to 3 per cent. grade and graded in to driveway to residence of Wm. Pearce; and said approach to be gravelled to prevent dust from blowing in on his residence, work to be done to satisfaction of Asst. Engineer of Board at Calgary. (b) In consideration of said reduction of grade, said Pearce consents to waive all claim for damages; and (c) Railway Company (G.T.P.B.L.Co.) dedicate land necessary for purposes of crossing, which is to be constructed in accordance with regulations of Board. And authorizing company to construct across Ninth Ave. and 26th and 30th Avenues, said City of Calgary, at its own expense.

19654—June 20—Authorizing C.P.R. to construct extension to existing spur on Lots 4 and 5 on north side of Chelsea Ave., at West Toronto, Ont., for Dearborn Drug & Chemical Works.

19655—June 21—Authorizing C.P.R. to construct three (3) bridges on Havelock Subdivision, Ont. Div., Ontario, namely: (1) Bridge No. 29.0, between Maberly and Ungave Stations; (2) Bridge No. 13.4, near Perth Station; and (3) Bridge No. 67.8, near Addington Station.

19756—June 19—Approving location C.N.R. station at Onoway, Alta.

19657—June 21—Authorizing C.N.O.R. to construct bridge to carry its railway over Raimbault Creek, Parish of St. Laurent, Co. Jacques Cartier, Que., mileage 48 from Hawkesbury.

19658—June 12—Authorizing City of Edmonton, at its own expense, to construct Shand Ave., across C.N.R., in said City of Edmonton, Alberta.

19659—June 20—Approving location C.N.R. station at Ardath, Sask.

19660—June 23—Authorizing G.T.P.R. to construct undercrossing on its main line, in N.W. ¼ Sec. 24-45-9, W. 4 M., at mileage 681.8 west of Winnipeg, Dist. North Alberta, Alberta.

19661—June 23—Rescinding Orders Nos. 16981 and 17785, dated respectively July 9th, 1912, and October 17th, 1912.

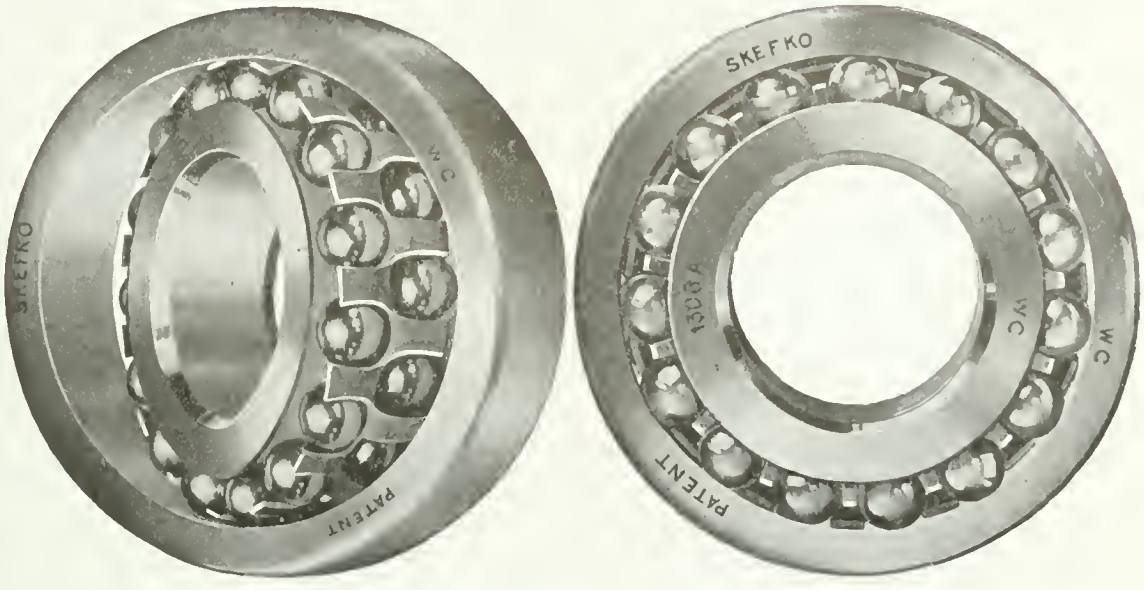
19662—June 21—Authorizing C.P.R. to construct spur for City of Medicine Hat, Alta.

19663—June 21—Amending Order No. 18736, dated Feb. 19th, 1913, to provide that gates be installed within 60 days from date of this order (at crossing of Montcalm St., St. Boniface, Man.)

19664—June 21—Authorizing C.P.R. to construct (1) two spurs across 15th St. East, and lands adjoining thereto, on north side of company's right-of-way, City of Calgary, Alta.; (2) a cross-over between above mentioned spurs; and (3) sub-spur in the block of land adjoining 15th Street East on its east side; spurs to be completed within three months from date of this order.

19665—June 24—Authorizing C.P.R. to operate trains through junction, mileage 5.94 on Ottawa Subdivision, at Breslay, Que., without first being brought to a stop.

No User of Ball Bearings Can Afford to Neglect these Points



1. **Double Row of Balls**—virtually two bearings in one, a splendid feature under any load condition.
2. **Pressed Retainer in One Piece**—made from Swedish Lancashire Iron. No rivets, wires or screws to work loose, jam balls, disarrange spacing or make noise.
3. **Outer Race Spherical**—providing for a frictionless self-alignment that absolutely and automatically compensates for shaft spring.
4. **Best Swedish Crucible Steel**—Carefully heat-treated and uniform in hardness throughout. Unequalled for toughness, carrying capacity, accuracy and durability.

SKEFKO

is the only truly self-aligning bearing. This feature alone is worth most careful consideration.
¶ SKEFKO Self-Aligning Double Row, Double-Capacity, Double-Life Ball Bearings cost no more and are made in international standard sizes. Their use is practical under any speed and load condition and the lubrication and protective housing can be made to conform to any service requirements.
¶ SKEFKO Bearings are the recognized standard and are replacing other constructions in many types of machinery.
¶ Our literature explains these matters in detail. Your best interests demand that you investigate. Tell us your bearing troubles and ask for our bulletins.

TENDERS CALLED FOR

PLANS AND SPECIFICATIONS ON FILE.

The following plans and specifications are on file for reference only, unless otherwise noted, at the office of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg, Man.

BIDS CLOSE		NOTED IN ISSUE OF
16-7	Construction of sewer and water-works, Prince Albert, Sask.	26-6

THE COMMISSIONERS OF THE TRANSCONTINENTAL RAILWAY.

NOTICE TO CONTRACTORS.

TENDERS FOR BUILDINGS AT COCHRANE.

Sealed tenders addressed to the undersigned, and marked on the envelope "Tender for Buildings at Cochrane," will be received at the office of the Commissioners of the Transcontinental Railway, at Ottawa, Ont., until twelve o'clock noon of the 22nd day of July, 1913, for the erection of an Ice House, Store House, Freight House, and two Tool Houses at Cochrane, Ontario.

Plans and specifications may be seen and full information obtained at the offices of Mr. Gordon Grant, Chief Engineer, Ottawa, Ont., and of Mr. T. S. Armstrong, District Engineer, Cochrane, Ont.

Tenders must be made on the forms supplied by the Commission, and be signed and sealed by all the parties to the tender, and witnessed, and be accompanied by an accepted cheque on a chartered Bank of the Dominion of Canada, payable to the order of the Commissioners of the Transcontinental Railway, for a sum equal to ten per cent. (10%) of the amount of the tender.

The right is reserved to reject any or all tenders.

By order,

P. E. RYAN,
Secretary.

The Commissioners of the Transcontinental Railway.
Dated at Ottawa this 24th day of June, 1913.

Newspapers inserting this advertisement without authority from the Commissioners will not be paid for it.—44403.

TENDERS WANTED.

Sealed tenders addressed to the undersigned, marked Tenders for "Incinerator," will be received up till 4 o'clock in the afternoon of the 29th day of July, 1913, for supplying all labor, tools, and machinery for the construction of an incinerator of a capacity to dispose of at least 25 tons per day of garbage and refuse. Incinerator must also be capable of destroying all kinds of refuse, including night soil and dead animals.

Contractors must supply their own specifications and designs, including brick or reinforced concrete building.

A marked cheque for 10 per cent. of amount of tender must accompany each tender, made payable to the order of the City Treasurer, which cheque will be subject to forfeiture in case of failure on the part of the successful tenderer to enter into a written agreement and bond with the City of Windsor with approved sureties when called upon to do so.

Incinerator must be guaranteed for at least one year from date of operation.

The lowest or any tender not necessarily accepted.

M. E. BRIAN,
City Engineer.

Windsor, Ont., July 3rd, 1913.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

TRENT CANAL.

Steel Pontoon Gate Lifter.

NOTICE TO CONTRACTORS.

Sealed tenders, addressed to the undersigned and marked "Tender for Steel Pontoon Gate Lifter, Trent Canal," will be received at this office until 16 o'clock on Tuesday, July 29th, 1913.

Plans, Specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Trent Canal, Peterborough, Ont.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the usual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque for the sum of $1,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Assistant Deputy-Minister and Secretary.

Department of Railways and Canals,
Ottawa, 25th June, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—44228.

NOTICE TO CONTRACTORS

Sealed proposals will be received at the offices of the Water Commissioners, City Hall, until 12 noon, July 31st, 1913, for the fabrication and laying of about 10¼ miles of 36-in. riveted steel pipe and appurtenances on the line of the Sooke Water Supply pressure conduit, and in accordance with the requirements of the general specifications prepared by Wynn Meredith, Consulting Engineer for such construction, pursuant to the provisions of By-law No. 814.

Plans and Specifications can be seen, and Forms of Tender obtained at the Sooke Water Supply Office, 1414 Douglas Street, Victoria, B.C.

The lowest or any tender not necessarily accepted.

C. H. RUST,
Water Commissioner.

Victoria, B.C., June 27th, 1913.

For further Tenders see page 86.

The Lowest Rate

It is not easy to obtain the lowest possible rate when insuring industrial buildings.

The time to consider the insurance cost is when the plans are being prepared for the building.

Architects can obtain the benefit of our highly-specialized knowledge of insurance ratings and fire protection, with the result that their buildings can be so planned that the insurance cost is as near "nil" as it could possibly be.

In the case of buildings already completed we will make inspection and suggest means of lessening the fire hazard that will likely more than pay for themselves by securing lower insurance rating.

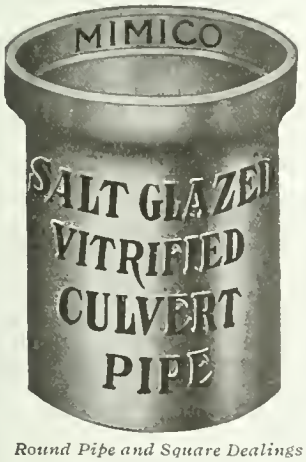
MIMICO BRAND
SEWER PIPE

Excellent clay, modern machinery, up-to-date kilns and—above all—CARE in every process, makes "Mimico Brand" the best vitrified, salt-glazed sewer pipe in Canada.



Round Pipe and Square Dealings

Have you written for your copy of our 1913 catalogue?

In the issue of June 26th, *The Canadian Engineer* said:

"The Ontario Sewer Pipe Company, Limited, of Mimico, Ontario, have issued a new catalog and price list that is very attractively and conveniently arranged. Besides containing photographs of the plant and of the various products of the company, price lists, tables of weights, thickness, etc., the booklet contains much information of a useful nature, such as the pressure of water at different elevations, the carrying capacity of sewer pipe, results of absorption tests, notes on sewer planning, etc."

Part III—DESIGN. (In preparation.)

TENDERS CALLED FOR

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

BEAUHARNOIS CANAL.

PROTECTION WORK FOR VALLEYFIELD GOVERNMENT DAM.

NOTICE TO CONTRACTORS.

Sealed tenders, addressed to the undersigned and marked "Tenders for works for protecting the Government dam at Valleyfield," will be received at this office until 16 o'clock on Friday, July 18th, 1913.

Plans, specifications and form of contract to be entered into can be seen in or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Quebec Canals, Montreal, Que.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque for the sum of $3,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,
L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 25th June, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—44229.

TENDERS.

CONCRETE BRIDGE AT SASKATOON.

Sealed tenders will be received up to 16.30 o'clock on Tuesday the 15th day of July, 1913, for the under-mentioned work:—

Construction of a concrete bridge over the South Saskatchewan River at Saskatoon.

Tenders for this work must be accompanied by accepted cheque on a chartered bank, or other satisfactory deposit for the sum of $15,000.00 Deposits of unsuccessful tenderers will be returned when contracts are signed.

The right to reject any or all tenders, or to waive any defects or irregularities therein is to be at the discretion of the Chairman of the Highway Commission.

Plans, specifications, forms of tender and all information may be obtained on application to the undersigned.

A deposit of $50 must accompany each request for copy of plans and specifications; this amount will be refunded on the return of plans.

A. J. McPHERSON,
Chairman, Board of Highway Commissioners.

Regina, Saskatchewan, June 20th, 1913.

(The unauthorized insertion of this advertisement will not be paid for.)

TOWN OF CARLYLE, SASKATCHEWAN.

WATERWORKS AND ELECTRIC LIGHTING.

Sealed tenders, addressed to the undersigned, will be received up till 18 o'clock on Friday, 1st August, 1913, for the following contracts:—

1.—Construction of brick power house and concrete reservoir, and laying approximately 800 lineal feet of pipe in trenches, and relative works.

2.—Supply of Air-lift Pumping System.

3.—Supply of Duplex Steam Pump.

4.—Supply and erection of two H.R.T. Boilers and Stack.

5.—Supply and erection of compound vertical steam engine.

6.—Supply and erection of Generator, Exciter, and Switchboard.

7.—Supply of poles, arms, hardware, copper wire, transformers and meters.

8.—Supply of Series Tungsten street lighting apparatus.

9.—Erection of Pole Line.

Tenders must be accompanied by an accepted cheque for five per cent. of the amount of the tender, or alternatively by the bond of an approved guarantee company.

Plans and Specifications and other information may be obtained at the offices of the Consulting Engineers at Winnipeg and Calgary. A deposit of $25 will be required on Contract No. 1, which will be returned to bona fide tenderers on return of the plans.

The Corporation do not bind themselves to accept the lowest or any tender.

F. J. STENT,
Secretary-Treasurer,
Carlyle, Sask.

The John Galt Engineering Co., Limited,
Consulting Engineers.

CITY OF SASKATOON.

TENDERS WANTED.

Sealed tenders, addressed to the City Commissioners, Saskatoon, and endorsed "Tender for Boulevard Posts," will be received until 12 o'clock noon on **Monday the 21st day of July, 1913,** for sixty cutter's 5-light Boulevard Posts No. 1121.

Specifications and form of tender may be obtained on application to Mr. E. Hanson, City Electrical Engineer, Saskatoon.

The lowest or any tender not necessarily accepted.

F. E. HARRISON, Mayor,
Chairman of Commissioners.

Saskatoon, Sask., June 25th, 1913.

EXTENSION OF TIME.

CITY OF VICTORIA, B.C.

Sealed proposals will be received at the offices of the Water Commissioner, City Hall, until 12 noon, July 31st, 1913, for the fabrication and laying of about 27½ miles of reinforced concrete pipe and appurtenances on the line of the Sooke Water Supply gravity conduit, and in accordance with the requirements of the general specifications prepared by Wynn Meredith, Consulting Engineer, for such construction, pursuant to the provisions of By-law No. 814, and adopted by the Council.

Plans and Specifications can be seen, and Forms of Tender obtained, at the Sooke Water Supply Office, 1414 Douglas Street, Victoria, B.C.

The lowest or any Tender not necessarily accepted.

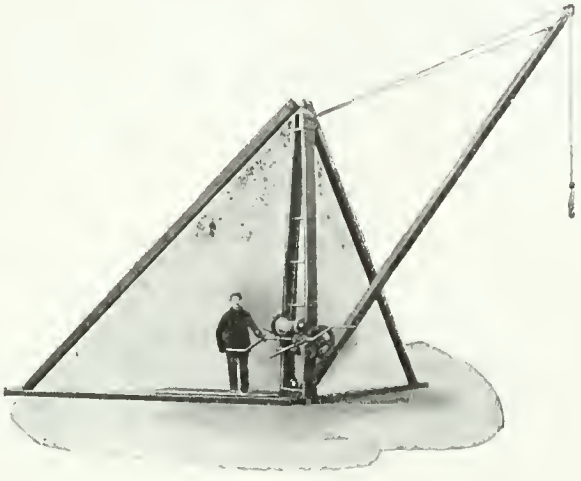
C. H. RUST,
Water Commissioner.

Victoria, B.C., June 14th, 1913.

For further Tenders see page 84.

BEATH SCOTCH DERRICKS

Hand or Power



THE construction of Beath Scotch Derricks embodies several points of merit not found in other makes.

All stress parts are **steel,** not cast iron. Bottom Pintle Bearing is of ball and socket type and works in a bath of oil, thus ensuring an easy movement at this joint.

Beath Derricks are provided with self-oiling bearings, ensuring easy operation and reducing wear to a minimum.

We also make Jinniwink Derricks, Stiff Leg Derricks, Guy Derricks, and Steel Derricks for heavy service. Hand or Power operated.

Send us your enquiries for Derricks

INTERNATIONAL ELECTRICAL CONGRESS.

Preliminary plans for the International Electrical Congress, which is to be held in San Francisco during the week beginning September 13th, 1915, in conjunction with the Panama-Pacific International Exposition, and under the auspices of the American Institute of Electrical Engineers, are being effected by the committee on organization.

In the week preceding the Congress there will be a meeting of the International Electrotechnical Commission.

The Congress is being divided into twelve sections as follows:—

1. **Generation, Transmission and Distribution.**—Central station and sub-station design, control and operation. Long distance transmission of electric power.

2. **Apparatus Design.**—Generators motors and transformers. Prime movers and their relations. The rating of machinery.

3. **Electric Traction and Transportation.**—City, surface and rapid transit railways; interurban and trunk lines; electric vehicles, ship propulsion, mining railways, elevators and hoists.

4. **Electric Power for Industrial and Domestic Use.**—Factories, mills, refrigeration, heating devices, etc.

5. **Lighting and Illumination.**—Arc and incandescent lighting; the science and art of illumination.

6. **Protective Devices; Transients.**—Switches, circuit breakers; condensers, electrostatics, disruptive phenomena, high frequency phenomena.

7. **Electrochemistry and Electrometallurgy.**—Electrolytic and metallurgical apparatus and processes.

8. **Telegraphy and Telephony.**—(a) All communication of intelligence by the use of wires; (b) Electromagnetic waves and radio telegraphy and telephony.

9. **Electrical Instruments and Electrical Measurements.**—Switchboard, portable, standard and absolute instruments. Testing and standardization methods; absolute measurements.

10. **Economics of Central Stations and Systems.**—Load factors, power factors and all problems affecting the economy of central stations; also rates and regulation by public service commissions.

11. **Electro-Physics.**—Radio-activity; Rontgen rays; gas and vapor conduction; electron theory; constitution of matter.

12. **Miscellaneous.**—Such as History of Literature of electrical engineering; symbols and nomenclature; engineering education and ethics.

In each section it is desired to include as many as practicable notable papers dealing with the status or the progress of the art. Offers of papers and suggestions in this connection should be directed to the Secretary of the Committee on Organization, Dr. E. B. Rosa, Bureau of Standards, Washington, D.C.

CURRENT NEWS.

Vancouver, B.C.—At a recent meeting of the civic water committee recently Dr. Underhill, medical health officer, reported as to the suitability of the soil from a sanitary standpoint for the proposed lake reservoir, which the city purposes making by the construction of a dam on the Seymour Creek. The health officer in his report stated that after an exhaustive test of the soil he found it free from all animal contamination, the area inspected being suitable for a storage reservoir. He expresses the opinion that he never saw a better natural site for a reservoir, the bed being composed of granite. He will make another test of certain portions of the area during the dry season.

Victoria, B.C.—Following the delivery of the Empress of Russia and the completion of the sister ship, Empress of Asia, by the Fairfield Shipbuilding and Engineering Company, for the Canadian Pacific Railway Company, the company are now taking tenders for the construction of two other large vessels to augment their Atlantic service. The vessels contemplated are each to have a length of about 550 feet and a sea speed of twenty knots, the turbine propelling machinery being capable of developing 24,000 s.h.p. Notwithstanding the high prices ruling, this is only one of the fairly numerous inquiries for high-class tonnage which are at present occupying the attention of British shipbuilders. Both Clyde and Tyne firms are quoting for the two new Canadian Pacific boats.

FOR SALE.—Complete Sewer and Water Contractor's outfit, including one Parsons' Trench Excavator, Trench Braces, Fire Pots, Pumps, etc. For price and terms apply to Navin Bros., Contractors, Moose Jaw, Sask.

$400 WILL BUY a 30 H.P. gas engine and 30 H.P. gas producer; used less than two years on a chopping plant. Israel Brubacker, Elmira, Ont.

FOR SALE—almost new, differential tackle and track; carry two tons. Canada representatives, 193 Spadina Avenue, Toronto.

FOR SALE—almost new, two 700-gallon cypress wood tanks with fittings, and 4 one hundred-gallon tanks on castors. Canada representatives, 193 Spadina Avenue, Toronto.

BOVING AND COMPANY, OF CANADA, LIMITED, PURCHASE NEW PLANT.

The business of the Canadian Boving Company is now being operated under the title of Boving and Co. of Canada, Limited, in order to bring the style into line with that of the other branches of Boving and Co., Limited, London, which are operating in Japan, New Zealand, Brazil, Mexico, etc. Owing also to the great increase in the volume of business and to their having purchased the works of Madison Williams Manufacturing Company of Lindsay, Ontario, the capital of the company has been increased to $1,000,000, a portion of the first issue having been found in Canada.

They are now in a position to turn out in their Canadian works the following machinery:—Water turbines, centrifugal pumps, pulp and paper making machinery, and sawmill machinery. Of these they had previously been making the centrifugal pumps in England, and the water turbines, pulp making and paper making machinery in Sweden, while the sawmill machinery has been manufactured by the Madison Williams Company in Lindsay.

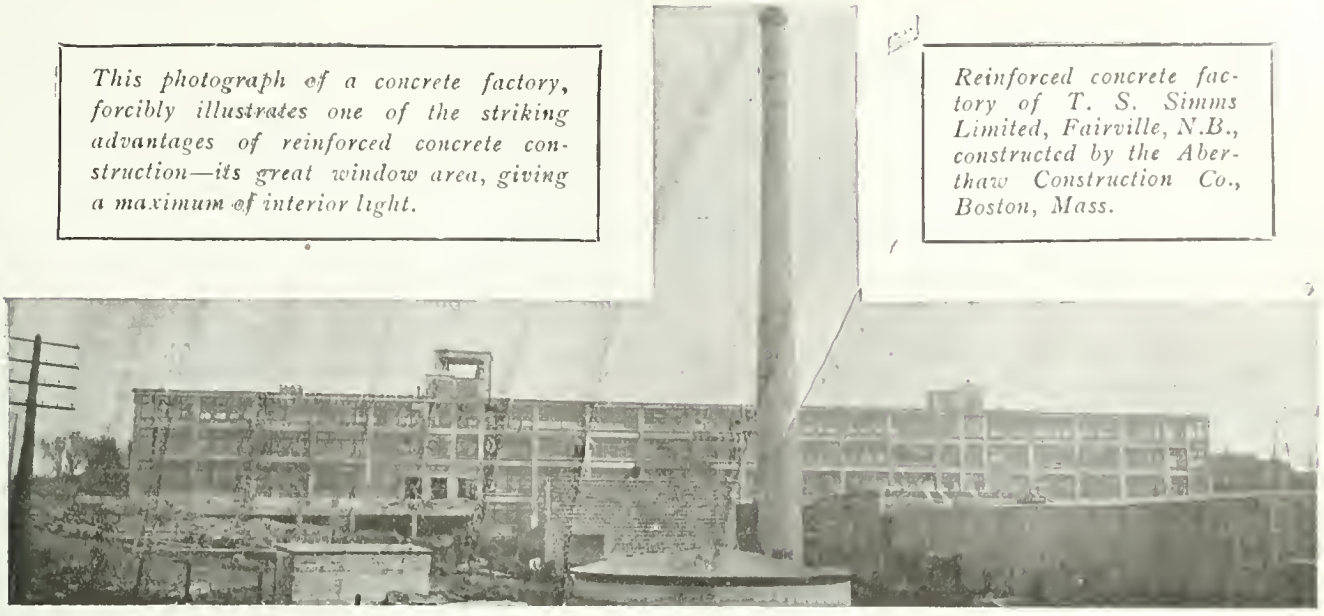
The Canadian Boving Company, Limited, completed their first large plant in Canada in 1910—viz., water turbines of some 8,000 H.P. for the Calgary Power Company.

The experience gained during the past three years by the company has enabled them to gauge the Canadian market, to familiarize themselves with what is actually required by and most suitable for that market, and by reason of their having let out contracts for various details of plants to Canadian firms they have been able to form an accurate idea of the cost of manufacturing such plants in the Dominion.

Their company is working in close alliance with Boving and Co., Limited, Union Court, Old Broad Street, London, England, to whose designs their machinery will be manufactured with such modifications as may be necessary to suit Canadian requirements.

This photograph of a concrete factory, forcibly illustrates one of the striking advantages of reinforced concrete construction—its great window area, giving a maximum of interior light.

Reinforced concrete factory of T. S. Simms Limited, Fairville, N.B., constructed by the Aberthaw Construction Co., Boston, Mass.



Concrete Factories are Most Efficient

The efficiency of a machine is the ratio of the amount of work a machine does, to the amount of work required to operate it. The output is equal to the input minus the work lost or wasted. The less wasted the greater the efficiency.
In the same way the efficiency of a factory may be defined as the ratio of output to input. Output, financially, is increased by reducing unnecessary expenses.

Concrete Stops Wastes

Concrete buildings are proof against fire, water and vermin. They give the maximum light and are sanitary. They resist vibration, and are permanent and durable.

Fire-proofness reduces insurance rates. Water or liquids used in certain processes will not leak through floors to destroy valuable goods below. Rats and other vermin find no place to live in a concrete building, thus eliminating losses from this cause. Maximum light and sanitary conditions increase efficiency of employees. Lack of vibration reduces wear and tear on machines. Permanency and durability reduce depreciation.

The way in which concrete stops these leaks is fully described in our handsomely illustrated 224 page book, "Factories and Warehouses of Concrete." It contains photographs and data of factories and warehouses for all classes of industries.

You can have a copy free if you will mention this advertisement.

LIMITED
MONTREAL

POSITIONS VACANT

Advertisements under this heading two cents per word per insertion. Minimum charge fifty cents per insertion.

WANTED.

By the city of Port Arthur, Ontario, **competent Ontario Land Surveyor** to act as Corporation Surveyor. Permanent position for the right man.

Apply giving experience, references and salary expected.

L. M. JONES,
City Engineer.

WANTED.—Experienced detailer and checker on highway bridge work. Applications, care of Box 56, *The Canadian Engineer*, Toronto.

POSITIONS WANTED

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

DO YOU NEED MALE HELP.—Canadian or foreign labor furnished for all classes of work, skilled or unskilled, for office, construction work, waterworks, paving, dams, and wharves. We can put men on the job for you cheaper than you can get them any other way, write or phone for particulars to O'Donnell's Employment Bureau, 116 Wellington Street West, Toronto. Phone Adelaide 3919.

YOUNG CIVIL ENGINEER (26) desires position with engineering firm or contractor. Technical education; six years' experience in city, hydro-electric and railroad survey, highway and concrete construction. Good transitman and draftsman. Have had charge of field and office work for past three years. Excellent references. Have own instruments. Box 42, *The Canadian Engineer*, Toronto.

GRADUATE CIVIL ENGINEERS of long and varied experience in this country and United States, desire work for spare time. Designing, detailing and estimating. Reinforced concrete structural steel a speciality. Box 46, *The Canadian Engineer*, Toronto.

MECHANICAL ENGINEER.—Experienced designer, cost estimator and salesman, works supervision, all kinds of steam engines. Boilers, hydraulic pumps, air machinery and mining plants, seeks position with consulting engineers, contractors, manufacturers or agency business. Highest references, some capital. Box 48, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER, " '07," with broad experience in designing and detailing steel and reinforced concrete, now employed as designer in Montreal, wishes work during evenings and spare time. Box 54, *The Canadian Engineer*, 628 Transportation Building, Montreal, P.Q.

CIVIL ENGINEER, thoroughly experienced in reinforced concrete design, steel framed buildings, foundations; competent to take full charge of design, estimate, and supervise construction, desires responsible position. Moderate salary. Available on short notice. Box 58, *The Canadian Engineer*, Toronto.

MECHANICAL AND ELECTRICAL ENGINEER desires position in charge of plant, or in firm of contractors. Ten years' experience in shop and power station. Used to all classes of boilers, engines, and high and low tension plant. Manufacturing and commercial experience. Box 60, *The Canadian Engineer*, Toronto.

ELECTRICAL AND MECHANICAL ENGINEER,—25 years' experience, desires superintending position. First-class references. Electric lighting, power, mining, or similar line of work preferred. Please address Box 62, *The Canadian Engineer*, Toronto.

COLLEGE GRADUATE CIVIL ENGINEER, neat draftman, wants work for his spare time. Designing, drawing, tracing, estimating, every thing in engineering line; lowest prices. Box 64, *The Canadian Engineer*, Toronto.

EXPERIENCED ENGINEER desires appointment, preferably as municipal or sanitary engineer. Technical education; twenty years' experience in the design and construction of drainage, sewerage and sewage disposal systems; street and road construction. Also limited experience in topographical surveys, water supply, town planning and plumbing design. Member of the American Society of Civil Engineers, and of the Royal Sanitary Institute. Please address replies in first instance to Box 66,, *The Canadian Engineer*, Toronto.

GRADUATE ENGINEER, five years' experience in railroad work, including heavy concrete work, steel and timber bridge construction, and heavy earth work. Box 68, *The Canadian Engineer*, Toronto.

ENGINEERING SALESMAN open for engagement. Excellent experience in selling mill power and mining machinery. Good references. Will be pleased to keep any appointment made through Box 70, *The Canadian Engineer*, Toronto.

POSITION WANTED, as general superintendent, assistant superintendent, or foreman, in building construction, by one with long experience in large work. Satisfactory references. Box 72, *The Canadian Engineer*, Toronto.

CONDENSED ADVTS

Advertisements under this heading three cents per word per insertion · Minimum charge fifty cents per insertion.

PATENTS FOR SALE Of the Canadian Patent No. 134013 and the United States Patent No. 1020197 for a very important improvement on **Link-Chains (Driving-Chains).**

Patented in 12 countries. Large success certain to be expected. Highest references from first-class firms.

ARNO GÜNZEL, Altenburg, S/A., GERMANY.

SARNIA WATERWORKS.

In connection with the recent ceremony of turning the first sod for considerable extensions to the waterworks of the town of Sarnia, Ont., it is interesting to note that the waterworks commission have finally decided to install steam turbine-driven pumps, after having spent considerable time in investigating all other types, including the vertical high duty type of pumping engine.

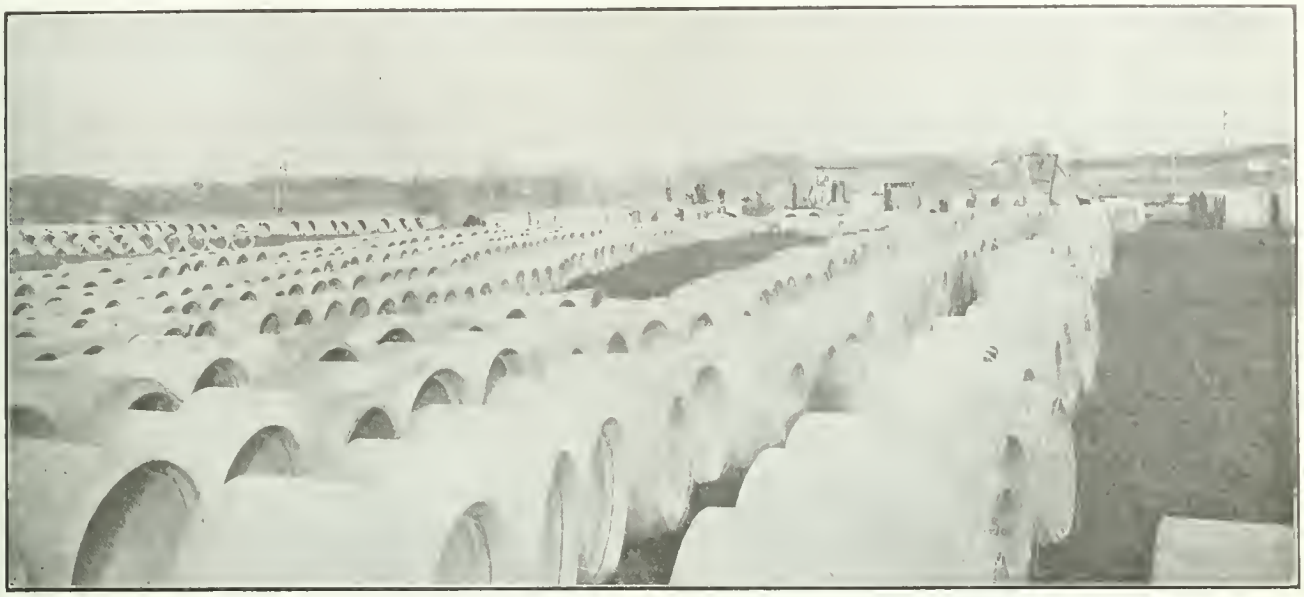
The available speed of the pump is 1,500 revolutions per minute, which is fixed by the fact that at some future time it may be required to connect the pump to an electric motor to operate on the Hydro-Electric 25-cycle supply. Herring bone gears are used to connect the pump to steam turbine operating at 3,600 revolutions per minute. By using this speed for the steam turbine, 20 per cent. less fuel is used than if steam turbines were run at the same speed as the pump. The gears are entirely enclosed in a cast-iron casing and are practically noiseless.

There are two similar units to be installed. The pumps are of Mather and Platt single-stage turbine type, each capable of delivering three thousand imperial gallons per minute against 200 feet head. The complete contract has been placed in the hands of the Canadian Allis-Chalmers, Limited, and will be manufactured at their Montreal works.

MERIWETHER SYSTEM

CONTINUOUS RE-INFORCED CONCRETE PIPE

PATENTED



Manufacturing 24, 30, 36 and 54 inch pipe for North Side Trunk Sewer, Watertown, N.Y.

LOCK JOINT PIPE COVERS NORTH AMERICA

Sewage flowing through Lock Joint Pipe reaches the Atlantic Ocean, Pacific Ocean, Gulf of Mexico, Hudson's Bay and the Great Lakes.

Lock Joint Pipe is in use for sewers and water conduits in the following States: Massachusetts, Connecticut, New York, New Jersey, Delaware, Pennsylvania, Maryland, Virginia, Kentucky, Georgia, Florida, Ohio, Illinois, Kansas, Washington, Oregon, Indiana, South Carolina, Missouri and Texas.

The following Provinces of Canada: Quebec, Ontario, Saskatchewan, Alberta and British Columbia.

And in the Island of Cuba.

The Lock Joint Pipe Company is the largest manufacturer of reinforced concrete pipe in the world.

MARKET CONDITIONS

Halifax, July 8th, 1913.

Axes.—Ordinary chopping axes, single bit, $6.50 per dozen; double bit, $11. Special brands, prices on application to jobbers.

Bar Iron.—The market for bar iron is open, but the situation is firm, and prices range as bigh as $2.35 base.

Black Sheet Iron.—This commodity is in good demand. We quote 24-gauge, $2.60.

Cast Steel.—The market is steady at 10 to 15c., according to makers.

Cement.—Stocks are low and market is steady, $2 per bbl.

Coil Chain.—The jobbing prices of English proof chain in Halifax are as follows:—3-16x4, $7.15; 7 16x3, $6.25; ¼, $5.35; 5-16, $4.60; ⅜, $4.35; 7-16, $4.20; ½, $4; ⅝, $3.65; ¾, $3.50; ⅞, $3.50; 1, $3.50; 1⅛, $3.50.

Fencing Wire.—We quote: plain twisted and galvanized at $3 per 100 lbs.; barb at $2.50 per 100 lbs.; bright staples in 100-lb. kegs at $2.65, and in 50-lb. lots, $3.15. Galvanized staples are 25c. extra.

Galvanized Sheet Iron.—The wholesale prices are as follows: 16 to 20-gauge, $3.85; 22 to 24, $4; 26, $4.50; 28, $4.75. These prices are for less than case lots.

Ingot Tin.—The tin market as usual is a fluctuating one, and the present price is about 60c. net cash.

Lead Pipe.—The price quoted to-day is about $6.65 for the ordinary jobbing quantities.

Linseed Oil.—Raw is fully worth $1.20 and boiled, $1.25 per gallon. Orders are small, the outlook firm, and higher prices looked for.

Nails.—Nails are firm. Wire nails, $2.45, and cut nails, $2.60. Business in this line is reported active.

Peavies.—There is a better enquiry than last year. Prices are unchanged at $11 to $13 per dozen, according to make, but we are advised that there will be an advance.

Pig Lead.—We quote $6.75 for English and $6.50 for Canadian.

Pipe.—Wrought iron, 1-in., $5.25.

Roofing Paper.—The demand is good. Tarred paper, $1.70 per 100 lbs.; three-ply, roofing, 90c. per 100 lbs.; two-ply roofing, 65c.; sheathing paper, 30 cents per roll; tarred sheathing, 40 cents per roll.

Rope.—The price of cordage for next spring's supplies is unchanged. For large lots dealers should write jobbers for quotations. Small lots are as follows: Sisal, 9½c. base; lolster rope, 9¾c.; British manilla, 9½c. base; best manilla, 10¾c., base.

Sheet Lead.—The price of sheet lead is also very firm, 3 lbs., and heavier, $6.25 per cwt., in rolls, and $7.25 in smaller quantities.

Steel.—Tire, $2.55; spring, $2.70; machine, $3.25; toe caulk, $3.50; sleigh shoe steel, $2.50; the above are all base prices.

Tin Plates.—I. C. coke, $4.50-$4.75; I. C. charcoal, $5.00; I. X. charcoal, $6.00.

Turpentine.—Prices now quoted are as high as $0.85 in bbls., and $1.05 to $1.15 in smaller quantities. The market is open.

White Lead.—For Canadian pure, in 50 and 25-lb. irons, $7.20 is being asked. Brandram's B.B. genuine in 25, 50, and 100-lb. irons, $7.85, and B.B. No. 1, $6.60.

Zinc.—This commodity is very firm, $8.25 for casks and 9c. pound for smaller quantities. Spelter is 8c. pound.

Montreal, July 5th, 1913.

In the first half of the year the United States made a remarkable record for production and consumption of iron and very little new buying. There is no indication of increased consumption, but much reason for believing new business will develop satisfactorily during last half.

The outlook for iron is better in most sections, on increased demand, but prices are still very low. In the south the extremely low quotations recently made have disappeared and prices are firmer, with considerable sold as high as $11. In eastern territory there has been more activity, and about 35,000 tons is pending in New York.

New York says that a considerable tonnage of pig iron has recently been sold. Inquiry is also in larger volume. Southern foundry, malleable bessemer, and charcoal prices fell from 25 to 50 cents per ton. Basic in Eastern Pennsylvania also went off 25 cents, but in the Valley no reduction took place. There is a growing disposition among merchant furnaces to reduce production and a number of furnaces have gone out of blast. In the Birmingham district, alone, four furnaces ceased operation recently, and several more may stop shortly.

There is very little change in steel conditions in the United States. Reduction in warehouse prices of steel is not regarded as significant. Dealers have been cutting prices on immediate delivery steel, and a readjustment on warehouse steel had been looked for for some time past. On future delivery, steel prices are firm. Reports of a better tone in steel abroad are encouraging, but these reports, unfortunately, are also denied.

The Montreal pig iron market shows very little change. It is doubtful if much American iron is reaching Montreal, but prices here are now on a basis to meet competition from the United States. It may be that a little Buffalo iron is reaching here, and, if so, the basis would be about $19.50 to $20 a ton, on cars.

English and Scotch iron is being offered to some extent, but it is not at all active. Some of it is being used for mixing purposes and prices range around $22.50 a ton on the dock for No. 1 Summerlea or Carron Iron. Selected Summerlea and special Carron is about $22, and soft Summerlea or Carron is $19.50. Some Clarence or Middlesbro' iron is probably changing hands around $19 on the dock. There have been reports to the effect that the price of $14 has been shaded in one or two instances at Buffalo, but this report is not altogether believed in Montreal. It is still possible to bring this iron into Toronto at $18.50, and this keeps the price of Canadian iron down.

The 300-ton furnace of the Canada Iron Corporation at Midland has been blown out and will be out of commission until about the middle of August. It is being re-lined, an operation which is apparently necessary every two or three years, the company, no doubt, taking the opportunity of the present low prices of pig iron to make the necessary repairs. The 150-ton furnace still continues to operate. With the exception mentioned, the probabilities are that the Canadian furnaces are operating full time. New business is being withheld until the situation in the United States clears up.

Prices hold very steady, being again unchanged, as follows:—

Antimony.—The market is firm at 10¼.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ¾ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Building Paper.—Tar paper, 7, 10, or 16 ounces, $2 per 100 pounds; carpet felt, $2.50 per 100 pounds; tar sheathing, 43c. per roll of 400 square feet; dry sheathing, 35c. per roll of 400 square feet; tarred fibre, 62c. per roll; dry fibre, 50c. (See Roofing; also Tar and Pitch).

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is unchanged, being now per 100 lbs., as follows:—¼-in., $5.30; 5-16-in., $4.70; ⅜-in., $3.90; 7-16-in., $3.65; ½-in., $3.55; 9-16-in., $3.45; ⅝-in., $3.40; ¾-in., $3.35; ⅞-in., $3.35; 1-in., $3.35.

Coal and Coke.—Anthracite, egg, $8.50; chestnut and stove, $8.50 per ton, net; furnace coal, $8.25, net. Bituminous or soft coal; Run of mine, Nova Scotia coal, carload lots, basis, Montreal, $3.85 to $4 per ton; cannel coal, $9 per ton; coke, single ton, $5; large lots, special rates, approximately $4 f.o.b. cars, Montreal.

Copper.—Prices are 16¾c. Excellent demand.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c, and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are: Queen's Head, $4.35; Colborne Crown, $4.25; Apollo, 10¾ oz., $4.25. Add 25c. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lead.—Prices are firm at $5.35.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Nails.—Demand for nails is active and prices are: $2.50 per keg for cut, and, $2.45 for wire, base prices. Wire roofing nails, 5c. lb.

Paints.—Roof, barn and fence paint, $1 to $1.25 per gallon; girder, bridge, and structural paint for steel or iron—shop or field—$1.45 to $1.55 per gallon, in barrels.

Pipe.—Cast Iron.—The market is active and strong:—$36 for 6 and 8-inch pipe and larger; $37 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 73½ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73½ per cent. for black and 63½ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, July 9th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Antimony.—Unchanged at $10.25 per 100 lbs., very firm.

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $10.

Building Paper.—Plain, 35c. per roll; tarred, 43c.

"FLEUR DE LIS"

Galvanized Iron

Will work as well as "Queen's Head." Not so heavily coated.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and ouff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, tor roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Coal.—Prices are quoted for this week as follows:—Youghiogheny lump, $3.85; river, $3.68; slack, $2.94; Solvey coke, $6.50; Connelsville coke, $5.45. Egg, stove and nut coke, $5.25. Pea, $6.75. Good market at these prices.

Copper Ingot.—The market is higher at 16 to 16¼c., sheet copper case (16 oz. soft), 23½ to 25¼c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cent.

Felt Roofing.—Fairly active at $2.10 per 100 lbs.

Fire Bricks.—English and Scotch, $30 to $35; American, $25 to $26 per 1,000. Fire clay, American, $8; scotch, $12. Market steady.

Fusee.—Electric Blasting.—Double strength, $3.50 per huodred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-ioch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-ioch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Lime.—Retail price in city 30c. per 100 lbs., f.o.b. car; in large lots at kilns outside city 25c. per 100 lbs. f.o.b. car without freight. Hydrated lime $10 per ton at warehouse; delivered, $10.60; 30c. per siogle bag at warehouse.

Lumber.—An active movement is going on ,of both timber and lumber, prices much the same as before. Pine is good value at $32 to $40 per M. for dressing, according to width required; common stock boards, $28 to $33; cull stocks, $22; cull sidings, $20. Southern pine dimension timher from $32 to $45, accordiog to size and grade; finished Southern pine, accordiog to thickness and width $34 to $48; spruce hemlock is in demand and held quite firmly, we quote $22 to $26; spruce flooring in car lots, $25 to $29; shingles, British Columbia, are steady, we quote $3.75; lath, No. 1, $4.60; white pine, 48-inch, No. 2, have gone up and are now held at $4.25; for 32-inch, $2.75 is asked.

Nails.—Wire, $2.30; cut, $2.70, spikes, $3.00 per keg of 100 lbs., base.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable eoquiry for 1912.

Putty.—In bladders, strictly pure, per 100 lbs., $2.60; in harrel lots, plaster is being used. Plasterer's, $2.15 per barrel of three bushels, at warehouse.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.50 per barrel.

Plaster of Paris.—Calcined, New Brunswick, hammer brand, retail price, $3 per barrel, and but small stocks on hand at warehouse. New York hydrated lime $10 per ton at warehouse.

Ready Roofing.—Prices are as per catalogue.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quehec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Rope.—Sisal, 9¼c. per lb.; pure manilla, 10¼c. per lh., base.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	0-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sires of angles and tees.

Sheet Copper.—23c. per lb

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.20; 22-24, $3.35; 26, $3.50; 28, $3.95; 29, $4.25; 10¾, $4.25 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 50 to 52c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Wheelbarrows.—Navvy, steel wheel, Jewel pattern, knocked down, $21.60 per dozen; set up, $22.60; Pan Canadian navvy, steel tray, steel wheel, $3.30 each; Pan American, steel tray, steel wheel, $4.25 each.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6.50 to $8 per cwt.

CAMP SUPPLIES

Evaporated Apples.—6c. per lb.

Butter.—Dairy prints are 23 to 25c. per lb.; creamery prints, 27 to 28c. per lb.

Canned Goods.—Peas, $1.35 to $1.75; tomatoes, 3s, $1.40 to $1.50; pumpkins, 3s, 85c.; corn, 97½c.; peaches, 2s, $1.50; strawberries, 2s, heavy syrup $2.40; raspberries 2s $2.15 with a tendency for lower prices on canned fruits.

Cheese.—New, large, 13¾ to 14c.; twins, 14¼c.

Coffee.—Rio, Green, 16c.; Mocha, 23 to 25c.; Java, 25 to 31c.; Santos, 17 to 18c.

Dried Fruits.—Raisins, Valencia, 8c.; seeded, 1-lb. packets, fancy, 8c.; Sultanas, choice, 10c.; fancy, 12c.; Filitras currants, cleaned, 7½ to 8c.; Vostizzas, 7¼ to 10c.; uncleaned currants, 7 to 7½c.

Eggs.—New laid, 21 to 23c.

Flour.—Prices are maintained; thus, Manitoba flour, first patents, $5.40; second, $4.90; strong bakers', $4.70; Ontario flour, winter wheat patents, higher, at $4 to $4.25.

Feed.—Bran, $25 per ton; shorts, $27 per ton, scarce.

Lard.—Tierces, we quote 14½c.; tuhs, 14¾ to 15¼c.; pails, 14¾ to 15¼c., tendency for higher prices.

Molasses.—Barbadoes, barrels, 35 to 50c.; West Indian, 27 to 30c.; New Orleans, 30 to 33c. for medium.

Pork.—Not much doing, short cut, $27 to $28 per barrel; mess, heavy, $22 to $23.

Rice.—B. grade, $3.33 per 100 lbs.; Patna, 6½ to 7c.; Japan, 6 to 7½c.

Salmon.—As before stated. We quote Fraser River, talls, $2.50; flats, $2.50; River Inlet, $2.35; cohoes, $2.20.

Smoked and Dried Salt Meats.—Long clear bacon, 15¾ to 16c. per lb. tuns and cases; hams, large, 18 to 18½c.; small, 20c.; rolls, 15½ to 16c.; breakfast bacon, 19 to 21c.; backs (plain), 24c.; backs (peameal), 24c.; shoulder hams, 13c.; green meats out of pickle, 1c. less than smoked.

Spices.—Allspice, 18 to 19c.; nutmeg, 30 to 50c.; cream tartar, 28 to 30c.; compound, 18 to 20c.; pepper, black, pure, Singapore, 19 to 20c.; pepper, white, 28 to 30c.

Sugar.—Granulated, $4.40 per 100 lbs. in bags; $4.45 in barrels, Acadia, $4.35; yellow, $4.30 per 100 in bags.

Syrup.—Corn syrup, special bright 3¾c. per lh.

Teas.—Japans. 22 to 35c. per lb.; Young Hysons, 16 to 35c.; Ceylons, 17 to 45c. per lb.

Vegetables.—Canadian potatoes, 75 to 80c.; Delawares, 85c. to 95c.; Egyptian, $2.75 bag; cabbages, 50c. dozen; apples, Winter, $2 to $3.25; turnips, 45c. hag; carrots, 65c.; parsnips, 75c. bag; beets, 75c. bag.

Winnipeg, July 8th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c.; anvil and vise combined, each $5.50.

Axes.—Chopping axes, per doren, $6 to $10.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kilo run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Building Paper.—Sheath, $1.10 per roll. Tarred felt, 8, 10 and 16 oz., $2.35 per 100 pounds. No. 1 tarred, 88c. per roll; plain, 72c.

Copper Wire.—Coppered market wire, No. 7, $4 per 100 lbs., No. 6, $4; No. 10, $4.06; No. 12, $4.20; No. 14, $4.40; No. 16, $4.70.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Hinges.—Heavy T and strap, per 100 lbs., $6 to $7.50; light, do., 65 per cent.; screw hook and hinge, 6 to 10 inches, 5¼c. per lb.; 12 inches up, per lb., 4¼c.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Lumber.—No. 1 pine, spruce, tamarac, 2 x 4, 2 x 6, 2 x 8, 8 to 16 feet, except 10 feet, $29; British Columbia fir and cedar, 2 x 4, 2 x 6, and 2 x 8, 12 to 16 feet, $32; 2 x 20, 4 x 20, up to 32 feet, $42.

Nails.—f.o.b. Fort William, $2.50; Winnipeg, $2.90; cut, f.o.b., Winnipeg, $3.35.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50: galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Roofing Paper.—60 to 67½c. per roll.

Shingles.—No. 1 British Columbia cedar, $4; No. 2, $3.50; No. 1, dimension, $5; No. 1, band saw, $6.

Spikes.—Basis as follows:—¼, 5 and 6, $4.25; 5-15 x and 5-16, $4; ⅜ x 6, 7 and 8, $3.80; ½ x 8, 9, 10, and 12, $3.65; ⅝, $3.55; ¾, $3.50.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Staples.—Fence, $2.50.

Timber.—Rough, 8 x 2, to 14 x 16 up to 32 feet, $38; 6 x 20, 8 x 20, up to 32 feet, $42.

Tool Steel.—8½ to 15c. per pound

The Canadian Engineer

An Engineering Weekly

THE DESIGN OF CENTRAL HEATING SYSTEMS

PART I.

STATIONS TO SERVE BUSINESS AND RESIDENTIAL SECTIONS HAVE MANY ADVANTAGES. ECONOMICAL AND AESTHETICAL FEATURES OF CENTRAL STEAM OR HOT WATER PLANTS.

By A. G. CHRISTIE, M.E.,
Assistant Professor of Steam Engineering, University of Wisconsin.

A LEADING consideration in discussing heating problems is the duration of the season in which heat is required and the degree of cold experienced during such periods. Experience with several heating systems in the State of Wisconsin has shown that the average season during which heat must be maintained on the distribution service extends from October 1 to June 1, a period of eight months.

Table I. shows the normal and mean monthly temperatures for Madison, Wis., over a period of years.

Table I.—Normal and Mean Monthly Temperatures at Madison, Wis.

Month	Normal Temp.	1906-07	1907-08	1908-09	1909-10	1910-11	1911-12
October	48.8	50	47	51	47	54	48
November	34.2	36	36	38	43	30	29
December	22.7	25	27	23	15	21	29
January	16.5	17	22	20	17	19	1
February	19.6	21	21	24	16	26	14.6
March	30.1	38	35	30	45	36	23
April	44.5	38	46	40	49	44	47
May	58.	49	57	55	53	63	58
Average	34.3	34.2	36.4	35	35.6	36.6	31.2

It can be seen that the year 1906-07 might be taken as approximately a normal season as far as heating demands are concerned.

Residence and Other Isolated Heating Systems.—In order to maintain comfortable living conditions in residences, offices, factories, stores, etc., during these cold months, it is obviously necessary to provide some means of artificially heating such rooms or shops. Usually this has been done in the past by providing individual heating apparatus for each building, which generally consisted of either a hot air furnace, a hot water heater, or a steam boiler, each with its accompanying heat distributing apparatus. Anthracite coal has been principally used, until recently, as fuel for burning in the furnaces of such heaters, largely on account of its cleanliness, its small ash content and its freedom from smoke. But the price of anthracite coal suitable for domestic purposes has now reached $9.50 per ton at Madison, Wis., and similarly high prices prevail in other cities and towns throughout the state. On account of this high price many householders and others are commencing to burn bituminous coal in their furnaces. Such coal can be successfully burned without smoke on only a few specially designed grates. It is therefore to be expected that as the price of anthracite is increased, the smoke nuisance in cities and towns will be aggravated by this increasing use of bituminous coal in domestic heating furnaces.

In a report on the work of the Smoke Investigation Committee at Pittsburg, Pa., it was pointed out that smoke not only results in losses to the coal consumer from the escape of unburned volatile matter, but also to the community as a whole through increased house cleaning bills, increased laundry bills, and damage to stocks of goods in stores and warehouses. Smoke limits plant growth, augments the persistency of fogs, decreases daylight and increases the prevalence of lung, throat and nose diseases among citizens of smoke-producing districts. In small cities these evils, though present, are not apparent to so marked a degree as in the large cities. Nevertheless, there are substantial reasons, as indicated above, for an active campaign for smoke abatement in any community, and such movements are now in vogue in all parts of the country.

In many cities steps have already been taken to minimize the smoke nuisance. Ordinances prohibiting chimneys from smoking more than a given number of minutes per hour have been passed, and smoke inspectors have been appointed to enforce these ordinances. Their attention has been principally directed towards the chimneys of large users of coal and to the locomotives on the railroads. Up to the present time little or no attention has been given to the chimneys of private residences. A short time ago the writer spent an early morning on a mountain top overlooking a large American residential city. The atmosphere was particularly clear that morning at daybreak and the homes of the city could be distinguished without difficulty by the naked eye. Just about sunrise coal fires were started in the furnaces of these houses and in an hour the whole city was obscured by a dense smoke cloud. The citizens of this city point with pride to their fine streets, beautiful homes and clean atmosphere, and are justified in doing so, while at the same time a long distance view of their locality showed that they made much smoke that they were not aware of.

Such conditions would be impossible with central station heating if the furnace designs at the station had been carefully made and the plant was operated intelligently.

Domestic heating apparatus needs attention in maintaining the fires, clearing out ashes, and cleaning and repairing the equipment before putting it into use each fall. These services are often not paid for in cash but are performed by the owner or one of his household. Yet there is a demand on such a person's time for this work. Then, again, there are also the many petty annoyances and irritations connected with the maintenance of the heating system which for comfort it is desirable to minimize or do away with entirely. Among such might be mentioned the fact that fires frequently go out when needed most, furnaces must be cleaned and fixed at the beginning of the season, coal gas escapes and is objectionable in the home or office and dust comes into the house from unloading coal and removing ashes and makes extra cleaning necessary. In apartment houses, the usually unsatisfactory janitor is practically eliminated when central heating service is supplied.

There is a tendency in such cases where individual furnaces are used to fire hard during the daylight and evening hours, and to bank the fires and allow the temperature of the building to drop during the night. This tends toward economy in fuel costs, although there is frequently a certain amount of physical comfort sacrificed for the sake of economy.

When hard coal is used, strict economy is practised. Storm windows and doors are put up after the first fall frost and from then on ventilation is sacrificed, while no space is heated that is not absolutely needed. This statement can be corroborated by any who have lived in rooming houses.

Many people follow the custom of purchasing the whole season's fuel supply during the summer months when coal is cheap. This often involves a certain degree of hardship as a comparatively heavy expenditure must be made at one time instead of having it spread out over a period of several months.

The Advantage of the Central Heating Plant.—Instead of providing individual heating furnaces in each building, a single building may be provided in a central location to accommodate the complete heat generating units for a given district, and heat can be transmitted to the different buildings by a system of underground pipes carrying hot water or steam. It is the purpose of this series of articles to discuss a number of phases of these central station heating systems in the light of personal experience and of the latest information available, especially with relation to conditions existing in Wisconsin.

When compared with individual heating plants, the central station systems have many points of superiority. Steam can be produced more economically in the large boilers in central plants than in small individual boilers. House heating boilers of 25 h.p. have shown efficiencies ranging from 40 to 50% under test conditions. Under average operating conditions such results would not be obtained continuously, and it is probable that the average operating efficiency is not far from 35%. Large sized boilers tested under actual daily operating conditions show efficiencies ranging from 60 to 80%, with an average of possibly 65%.

To illustrate some results that are actually obtained in a central heating plant of the best design, the boiler efficiencies obtained from three different tests of the boilers of the Capitol Heating Station at Madison, Wis., are as follows: The first two tests were made on single 400 h.p. Stirling boilers fitted with Murphy stokers. Boiler efficiencies of 80.9 and 82.9% respectively at nearly full load rating were obtained from these tests. A year after the first tests, a trial was made on two boilers together, with less than half load on each, with a resulting boiler efficiency of 66.2%.

Other results of considerable interest are from tests made in 1911 by Messrs. Pugh and Watson, seniors in the College of Engineering, forming a portion of their work for the degree of Bachelor of Science in Mechanical Engineering. The tests were made on several of the 350 horse-power B. & W. boilers at the University heating station at Madison, Wis. Their object was to determine the efficiency of operation and the rate of evaporation of the various boilers under actual operating conditions. The boilers under test were fired by the regular crew in the same way as all the other boilers in the plant, so that the results represent average conditions of operation. These trials showed boiler efficiencies ranging from 64.6 to 77.3%, depending on the amount of scale on the heating surfaces and the particular type of furnace construction installed under the tested boiler.

It can thus be seen that there is a difference in efficiency under average operating conditions in favor of the central station of from 75 to 100%.

A table in Bulletin No. 40 of the Bureau of Mines gives the details of operation of fifty-seven central heating plants. In commenting on the costs of service, the authors state as follows: "A comparison of the prices charged by central stations as given in this table with the cost of fuel only for an ordinary house heating boiler shows that in many cases the cost of producing heat on the premises equals the price charged by the central stations. When heat is purchased the customer avoids the annoyance of having to supervise the operation of the heating plant as well as of the dust resulting from the delivery of fuel and the removal of ashes."

In the central station smoke can be almost entirely eliminated by the frequent firing of small quantities of coal on properly designed grates. Slack and other cheap grades of bituminous coal can be used instead of the more expensive grades supplied for household furnaces. It is also possible to install such sized boilers at the central station that those in service may operate at maximum economy at all times. It is therefore apparent that the central station can effect considerable savings over individual plants so far as boiler operation and coal are concerned.

The savings already mentioned are offset to some extent by the fact that the central heating system is expensive to install and thus a heavy overhead charge must be made on the service rendered to meet interest, maintenance and depreciation charges on such distribution apparatus. At the same time, an operating force must be employed at the central station.

When a prospective customer undertakes to compare central station charges for heating with the cost of his individual service he usually considers only his coal costs and neglects to allow for the interest, maintenance and depreciation charges on his own furnace equipment, which would be rarely less than about $15, even in the smallest houses.

When central station heat is used, the fire risk on property is diminished and hence insurance rates are

lowered. The property becomes more desirable on account of his heating service and, therefore, can command a higher price if one wishes to sell. It has also been found that in residences with such connection it is easier to secure and keep servants. These considerations are of considerable economic importance to every property owner and householder in a city where district heating is proposed and should therefore receive the careful consideration of the prospective customer.

That the central heating station is receiving considerable attention of late is evident from the following quotation from Bulletin No. 40 of the Bureau of Mines, which states: "The central heating plant is not a new thing; in fact, some of the plants have been in operation for twenty to twenty-five years. Development in this direction has been very slow, however, until within the last five or six years, when the idea has received renewed attention." A table in the same bulletin gives data on 57 plants throughout the United States in 1907, and from this table it is evident that the plants are most numerous in the States where coal is relatively cheap. It will be shown in a later part of this article that a very considerable portion of the cost of central station service is the overhead charges on the distribution system, and this proportion increases as the price of coal decreases. It is therefore apparent that in these cities where coal is cheap the citizens prefer central station service for other reasons than economy in fuel cost. If, under such conditions, this service has certain acknowledged merits to commend its use, it seems hard to understand why it has not been more widely adopted in localities where coal is expensive and where the distribution costs would form in consequence a smaller proportion of the charges for central station service. It seems evident that the value of this service will be recognized in the near future and that in consequence the number of central heating plants will increase quite rapidly.

Isolated plants in large office buildings, stores, hotels, factories, etc., are able to furnish the necessary heating, together with the power and light required, at a low combined cost. If a central heating company wishes to secure such business, it must be prepared not only to supply heat but also electricity under more favorable conditions than would the isolated plant. This may not necessarily mean at a lower cost, for many executives are willing to pay for the relief from the care and anxiety incident to the installation and maintenance of a steam-electric power plant.

The Central Heating System as a Public Utility.—A central heating system must be considered as a public utility, and it therefore comes under the control of the "Public Utility Commissions" in such states as these exist. In Wisconsin public utilities are controlled by the Railroad Commission.

The methods employed by the commission in making its valuations are of very great interest and deserve the careful study of all engineers engaged in public utility work. There have been no rulings up to the present time on any case involving district heating, so that there has been no fixed rate of return recognized. In the case of utilities supplying electricity, 8% profit on the entire valuation has been taken as a basis for ratio-making. The books of all public utilities must be kept according to methods and forms prescribed by the commission.

Public utility corporations in the State of Wisconsin are so regulated by the commission representing the state that they are true servants of the public. At the same time the guarantee of a fair return on capital honestly invested has so enhanced the value of the stocks and bonds of these corporations that they are now considered "gilt-edge" on the stock markets.

These laws have been extracted at some length to make perfectly clear the conditions that would be imposed on a corporation that proposes to organize and do a central station heating business in the State of Wisconsin.

The property of a public utility corporation can be assessed at an appraised value by the commission and taxed for municipal and state purposes in the same manner as other real property.

The corporation is required to report at regular intervals to the commission on forms provided for such purposes. These reports cover service records and financial statements.

There are greater natural limitations to the extent of the service of a heating station than in the case of an electric plant. The distance over which heat can be transmitted cannot compare with the transmission of electricity owing to the higher first cost of the underground distribution system and the greater power lost in forcing the heating medium—either steam or hot water—to the outlying portions of a long system. There will be a certain radius around the central station over which heat can be supplied to customers at a reasonable cost after allowing a fair return on the investment.

The greatest distance over which heat can be transmitter from a central station is determined by the allowable friction losses in the mains and the amount of service at the end of the line. Mr. Chas. R. Bishop, in a paper before the New England Section of the National Electric Light Association, stated that in general this radius of distribution should be from one to one and three-quarter miles from the central plant. From data pertaining to the heating stations in the United States, it would appear that a reasonable radius of distribution is from 4,000 to 5,000 feet.

Plant Location and Design.—In considering plant location and design, it is of first importance to determine the probable extent of the heating service, for on this depends the entire design of plant equipment and underground pipe lines. The central business portions of cities and the more thickly populated well-to-do residential sections will provide the greatest heating loads for the least capital expenditure.

When a central heating plant is under consideration, a careful examination should be made of all territory, both business and residential, that it is proposed to serve, and a scaled map of this section should be prepared. The distance to the extreme portions should not exceed about two miles from the station. The type of each building (whether wood, brick, concrete, etc.) should be noted on this map, together with the classification of the use to which the building is put, as, for instance, stores, residences, theatres, hotels, etc. The next step is to secure weather records of the city or of a neighboring city. Then the maximum and minimum temperatures throughout the heating season should be plotted. From these curves it is possible to select other cities where similar conditions prevail, and data should be secured from those cities as to the maximum and average heat demands for each type of structure in such a town. This information should be applied to each block or section of the town in question and the results will form a fair estimate of the probable requirements that must be met by the proposed heating system. The design of mains from the station may now be commenced and the proportions of these should be such as to

meet modern engineering requirements for such service. The complete system for which the plans were made need not be installed during the first season. The plans, however, should always be made for the ultimate installation capacity. Otherwise, the system would become inefficient as the load increases.

Theoretically, the central heating plant should be located at or close to the centre of the area over which heat is to be distributed. But this location is often out of question in an actual case owing to high costs of real estate, poor facilities for handling coal and ashes, lack of suitable water supply, and the location elsewhere of existing plants whose facilities will be utilized. A high first cost of real estate for the plant places an initial heavy overhead charge on the service, though this may sometimes be offset by other economies to be gained by a central location. Neighboring property owners frequently object to the location of such a station adjacent to their buildings on the plea that the attendant noise, dirt and smoke will tend to lessen the value of their holdings. The New York Edison Company has had to defend several suits for damages due to alleged injury to surrounding property from soot and cinders which were discharged by the smokestacks during periods of heavy loads. The Murphy Heating Company, of Detroit, on the other hand, have located their central station near the heart of the business district instead of on the river front. In general, however, it is not advisable to buy an expensive site even in a centralized location unless there are special considerations that make such a site more desirable than any other one available.

The cost of handling coal and ashes at the central station must be a minimum if low operating costs are to be obtained. This is more nearly possible when the plant is located beside a railroad or a dock so that coal cars may be switched to or unloaded into the station itself. When coal has to be trucked a considerable item is necessarily added to the costs of operation, and thus to the heat sold to customers. The saving of such charges will very frequently greatly offset the extra losses in pipe lines reaching to the distributing centre from a less central location.

A central heating plant, especially one using a low-pressure steam distribution system where the condensed steam is wasted to the sewers, uses a large quantity of water daily. It is desirable that such a plant should have access to a water supply independent of the city mains, either by means of a small pumping plant on a nearby lake or stream or by artesian wells. When the plant contains electric generating equipment which is run condensing during the summer season, large amounts of water must be at hand for cooling purposes. Such possible water demands should receive careful consideration in connection with the location of the plant.

In a later part of this series, it will be shown that the losses in distribution systems vary with the length and size of the pipe lines. Hence a central location is the most desirable from a distributing standpoint, for then the heating load can be secured by comparatively short pipe lines throughout the district it is proposed to serve and these lines can radiate in all directions from the plant. This would result in minimum heat losses and would also provide a more uniform pressure over the whole system provided the pipe lines were properly designed.

Systems for Distributing Heat.—Heat may be distributed from a central station either by means of hot water or by low pressure steam. At the present time there is a considerable difference of opinion regarding the relative advantages of these two systems. It is not intended in this thesis to advocate either system but rather to discuss the application of both in central heating practice.

Flow and return pipes must be provided in the hot water system. The return water enters the plant at a lowered temperature, passes through some type of re-heater and is then forced out through the system again by pumps. Several types of re-heaters utilizing the exhaust steam from engines are in use. Hot water systems are spoken of as "closed" or "open." On the former system closed heaters are used and the pump forces the return water through the heater and out into the flow pipe. By attaching a condenser with an air pump in series with these heaters, it is possible to carry any degree of vacuum desired. Live steam heaters in series with the exhaust heaters are also in common use for meeting peak loads. Sometimes it is desirable to place these above the level of the boilers so that the condensed steam flows back by gravity. The amount of heating to be supplied by this heater is adjusted by throttling the steam supply. Frequently a number of the boilers in the plant are so piped up that they can serve as water heaters.

The "open" system of hot water heating operates with open heaters or with a type of barometric condenser called "co-minglers." In the latter the exhaust steam and return water mix together and are drawn off by the circulating pump connected to the tail pipe which discharges the mixture into the heating system. The condensed steam goes to make up the losses in the system from leakage, while the excess is used as boiler feed. With the closed system the condensed steam from the re-heaters is pumped back into the boilers. The open system requires more power to circulate the water than the closed system as the return static pressure is necessarily lost in the vacuum of the co-mingler or in the open heater. The selection of the open or closed system depends largely on local conditions. When engines are used, and it is desired to carry a vacuum, the co-mingler would be the logical choice though other systems are also used for the same purpose.

Vacuum and pressure systems are both in use for distributing steam heat. In the vacuum system two pipe lines are installed—a large pipe to carry the low pressure steam to customers' installations, while a smaller one under vacuum acts as a return for the condensed steam to the plant. It is possible at times to operate this system with a partial vacuum at the engine exhaust, thus increasing the power and economy of the engine. The condensed steam is all returned to the plant and can be used again for boiler feed water. In some localities this item is of considerable importance.

The pressure system consists of a single pipe line with a steam pressure between 3 and 10 pounds about atmosphere. The condensed steam is usually metered at the customer's premises and wasted to the sewer. Exhaust steam from engines is generally used on this system, augmented when necessary by live steam passed through reducing valves. This is the simplest system of all.

It seems generally agreed with regard to the first cost of plants that both the station and distribution equipment of the steam pressure system can be installed for less money than the vacuum or either hot water system. On the other hand, the piping must be better insulated to prevent excessive line losses as the steam temperature is higher than if hot water or vacuum systems were used.

Steam is capable of furnishing such general service as cooking, laundry work, etc., which water will not do. Steam can be adapted to customer's hot water installations already in place, either directly or through reheaters, and can be applied to hot air systems by means of indirect radiators. Hot water, on the other hand, cannot be successfully applied without alteration to steam systems which are already installed.

When the cost of operation is considered, hot water systems have the advantage that partial vacuums can be carried on the engine exhaust. However, as the load factors are usually low in electric stations, it is advisable in all cases—as will be pointed out later—to figure the plant for the production of heat alone, in which case this apparent advantage largely disappears. Higher circulating pressures must be maintained on hot water systems than with steam. Hence heavier and more expensive pipe lines and fittings must be installed.

The elevation of the area to be served in relation to the plant location, and also the height of the highest building to which heat is furnished, will determine the pressure to be maintained on a hot water system. This is usually about 15 pounds above the static pressure at the plant. If a city is hilly, then the hot water system cannot compare favorably with steam on account of excessive pressure in the pipes, the power required for pumping and the friction losses in the system.

Some device must be employed on hot water systems to regulate the amount of water flowing through the customer's radiators. Valves with adjustable openings controlled by a special key are sometimes installed. On other systems choking discs or nipples are inserted in the return pipes and also at each of the radiators. The holes in these are so proportioned that only the proper amount of water will be forced through the radiators by the prevailing pressure.

Hot water lends itself more readily to temperature regulation than steam. With the latter some form of thermostatic control must be employed, while with hot water a schedule of flow temperature to be maintained at the central station can be prepared for varying outside temperatures and wind velocities. In this way the customer receives heat in just the right amount to avoid overheating his rooms in any kind of weather.

The amount of steam used by various customers can be determined by metering the condensed steam and charges for service may be based on this amount. The customer then pays for the heat used and may be as economical or wasteful as he desires. In such systems cooling or economizing coils with 15 to 20% of the total radiation capacity should be installed by each customer to recover the heat in the condensed steam before discharging it through the trap and meter to the sewer. This is an absolute necessity in some cities where citizens are prohibited by ordinance from discharging water into the sewers above 125° F. or so.

Hot water service, on the other hand, cannot be metered, and charges for the same must be made on the basis of square feet of radiating surface or on some other flat rate basis. In actual service it has been noted that where there is no financial incentive to economy 25 to 50% more heat will be used than is actually required. As a result of this, all flat rates must be higher proportionally than metered service, and so the economical customer helps to pay for the carelessness and extravagance of others.

As a rule, steam service is more popular in business sections, while in residence districts hot water seems to be more generally sought.

When a customer has his residence or building piped up for hot water and the district heating system supplies steam, all that is necessary to secure central station service is to install some form of heat transformer or interchanger, of which there are many on the market. These devices consist, as a rule, of double tube manifolds with the steam supply connected to the inner tube while the hot water circulates between the tubes. The steam in condensing gives up its heat to the water which rises and establishes a circulation in the same manner as when a coal-fired heater is used. The condensed steam can be metered and charged for in the usual way. Kitchen and bath heaters can also be piped up to one of these heat interchangers, or a coil of pipe carrying steam can be placed in the water reservoir itself.

Some schedule of service for varying outside temperatures should be prepared for the guidance of the central station operators with either hot water or steam systems. For the former, tables of flow temperatures to be maintained at the central station should be prepared, with corrections to be applied for various velocities and directions of wind. Such a schedule of temperatures is shown in Table II., and applies to a central hot water heating station in Columbus, Ohio.

Table II.—Relation Between Outside Temperature and Hot Water Flow Temperature.

Temperature. Weather.	Flow.	Temperature. Weather.	Flow.	Temperature. Weather.	Flow.
70 above	stopped	36 above	157	Zero	210
68 "	106	34 "	159	2 below	212
66 "	112	32 "	162	4 "	215
64 "	117	30 "	165	6 "	218
62 "	121	28 "	170	8 "	221
60 "	125	26 "	175	10 "	224
58 "	128	24 "	178	12 "	226
56 "	131	22 "	180	14 "	229
54 "	133	20 "	184	16 "	232
52 "	135	18 "	187	18 "	235
50 "	137	16 "	189	20 "	237
48 "	139	14 "	191	22 "	240
46 "	141	12 "	194	24 "	243
44 "	144	10 "	196	26 "	246
42 "	147	8 "	198	28 "	249
40 "	150	6 "	201	30 "	252
38 "	154	4 "	204		
		2 "	207		

The above schedule is to be applied in still weather only. With falling outside temperature and a wind of 12 miles per hour add 5 degrees; with falling outside temperature and a wind of 18 miles per hour, add 10 degrees.

[A second part of this article, dealing with the design of heating stations, pipe lines and conduits, will appear in the next issue of *The Canadian Engineer*.—Ed.]

Drills of hard electric steel have recently been adopted in connection with the boring machines employed by the State mining authorities in the Goslar district of Germany. The result is stated to be not only an increased output, but a marked reduction in the number of replacements necessary, and also in the number of drills that require sharpening.

THE FIRE HAZARD IN TURBO-GENERATORS.

By G. S. Lawler,
Elec. Engr., Inspection Dept., Assoc. Mut. Fire Ins. Cos., Boston, Mass.

THAT there is a great chance of serious damage by fire, following arcing in turbo-generators, and suggestions for minimizing this hazard form the subject of a paper by Mr. Lawler appearing in the July number of the Journal of the American Society of Mechanical Engineers.

The chances of electric generators of the older types being seriously injured by fire in the event of some part of the insulation failing is slight. Occasionally arcing will ignite the insulation at some point, but it is seldom that the fire will spread much before it is extinguished. This freedom from fire damage is due principally to the comparatively low speeds, the accessibility of the combustible insulation, and the fact that the machines, being of large mass per unit capacity, the insulation is considerably distributed.

This condition of practical freedom from fire is reversed in the case of generators of the turbo type, for when a short circuit occurs in one of them there is a great chance that the insulation will be ignited and the machine be badly damaged; in fact such damage has occurred in a number of instances.

The chief causes of the increased hazard in the more modern type generators are as follows:—

1. The volume occupied by this type of machine is very much less for the same capacity than that of the older types of generators, so that the combustible insulation is more concentrated and, therefore, much of it is exposed, even to a slight arc or fire. The covering on the conductors depends greatly for its insulating qualities on the presence of oils or gums of a highly combustible nature. The amount of this combustible insulation on the higher voltage generators is naturally greater than in the low voltage machines.

Owing to turbo-generators having only a few poles the end connections between slots form a large proportion of the total length of conductors, in fact in some designs approximately one-half of the coils are outside of the slots. These end connections, one-half being on one side of the machine and one-half on the other, are exposed to fire, and as with a pile of loosely laid sticks, fire will rapidly extend from the insulation on one coil to that on the others.

2. Owing to these generators being of exceedingly large capacity in many instances, (one of 30,000 kva. capacity now being constructed) an enormous amount of energy is involved in a short circuit, especially at the instant the short occurs and as the arc is confined in the limited space with the combustible insulation, it would seem impossible for the insulation to escape being set on fire at many points simultaneously.

3. The machines are cooled by forcing large quantities of air through the spaces between the conductors. The large and constantly renewed supply of oxygen will hasten combustion when it is once started.

The air is given somewhat of a rotary motion by the rapidly revolving rotor which has the ventilating vanes on it and consequently fire when started will be quickly swept around the exposed insulation.

4. The generators are totally encased with the exception of the air inlets and outlets and even these in some designs are under the machines. This construction prevents access to a fire and much valuable time will necessarily be consumed before extinguishing agents can be used effectively. When the field current is cut off, as is necessary in case of short circuit, the only means of bringing the rotor quickly to rest is lost and it will continue to run for a long time after the steam has been shut off. Some machines will run for over an hour. This continued rotation is not conducive to the quick extinguishing of fire, especially when the ventilating vanes are mounted on the rotor.

In addition to the possible causes of arcing existing in the case of the older types of generators, the turbo-generator is subject to momentary large current rush at instant of short circuit, even if the short is external to the machine itself, unless means are taken to keep the current within safe limits. The heavy rush of current causes mechanical stresses in the conductors, which in some cases are severe enough to distort the conductors, especially where outside the slots, and to injure the insulating covering, resulting in a short circuit within the generator itself. In some designs the internal reactance of the machines will permit of the momentary current rush amounting to 40, or possibly more, times the normal full-load current of the machines.

The possibility of the conductors being distorted has been reduced in some cases by designing generators with sufficient internal reactance, or by providing external reactance such that the current at the moment of short circuit will not be great enough to damage the generators. Attention has also been given to supporting the stator end connections to prevent their distortion. These means have undoubtedly greatly increased the safety of the turbo-type of generator from possibilities of internal short circuit, but in no way tend to prevent a fire resulting should an arc occur.

A short circuit in the rotor will probably not result in a severe fire unless under exceptional conditions. This is also true if the short circuit occurs inside of a stator slot. A short circuit involving a stator coil, however, is more apt to occur at the end of the slot where the conductors are exposed.

As asbestos is now used largely for insulating the rotor windings and as these windings are well protected, it is probable that only in cases of severe fire in a machine will the rotor windings be damaged to any extent.

While the generators may be free from fires during the earlier portions of their life owing to the proper use of reactances which prevent external troubles seriously affecting the machines, as they get older the ordinary causes of breakdown of insulation are liable to occur and fires result. Probably in most cases generators will not be discarded until some trouble, usually in the nature of a short circuit, has occurred at least once in each, so that it is reasonable to expect that unless further preventive means are taken, turbo-generators stand a good chance of serious damage by fire at some time during their life. Although many fires have occurred, probably most of them have happened during the generator development stage. Generators of the turbo type are of such recent production that none of them has yet reached a life which could be considered old and, therefore, the troubles which can be expected near the end of their life by fire have still to come.

Undoubtedly the manufacturing companies have given serious thought to the matter of the reduction of the fire hazard in turbo-generators and have employed all

means practical at the present time to this end, but there is still very much to be desired. The following several means if taken together would seem to minimize the chances of a serious fire:

1. If a suitable material could be found a non-combustible outer covering could be placed over the insulation on the stator end connections. This would greatly delay the spread of fire and even if no other protective means were taken, would undoubtedly prevent much serious damage. Where fire extinguishers were used the covering would at least hold back the fire until they could be brought into play. At present no material suitable for such a covering appears to be available.

2. If a non-combustible outer covering should be put on, its advantages would be partially lost in time unless the cooling air were freed of the dirt and oily vapor liable to be in it. This could be done by filtering, as has already been advocated several times.

3. Means could be provided for cutting off the air supply in case of fire in generators by placing dampers in the inlet ducts designed so as to be normally held open by fusible links. The links could be placed so that they would be quickly fused by the heat and allow the dampers to close automatically. By reducing the oxygen supply to that entering by leakage the action of the fire would be slow.

4. Arrangements could be provided for the quick introduction of carbon dioxide gas into the machines. The carbon dioxide could be kept in liquid form and piped through valves, expansion tanks, etc., to the generators. The valves could be arranged to be opened by the closing of the air inlet dampers so that the gas would be automatically introduced into the generators. This gas would be very effective in extinguishing fires inside the machines after the air supply had been cut off.

The employment of some efficient method of reducing the fire hazard in generators of the turbo type either along the lines mentioned or in some other way is important. The value of these generators is great and the damage by fire may amount to a considerable proportion of the first cost. It is probable that the damage is more liable to occur towards the end of the life of the generators, but even then the loss may be large, both directly and indirectly. The large central stations have reserve units so that the increased damage due to fire in one of their generators would probably not affect the continuity of service, but the increased time necessary for repairs may be long and during this time the reserve capacity will be weakened. In the case of industrial plants the longer time needed for repairs might be serious. Many manufacturing concerns who generate their own current depend on only one unit and, therefore, their whole production, or a large part of it, would be affected.

UTILITY AND ATTRACTIVENESS IN ECONOMIC RESERVOIR DESIGN*

DESCRIPTION AND DESIGN OF A CIRCULAR REINFORCED CONCRETE RESERVOIR, 200 FEET IN DIAMETER, 26 FEET DEEP, WITH SIDE WALL WHOLLY ABOVE GROUND.

By ALEXANDER POTTER,
Consulting Engineer, New York City

MUSKOGEE, Oklahoma, takes its water supply from the Grand River. The present intake is located in the channel of the river, about 1,800 feet above its confluence with the Arkansas River. Two 16-inch cast iron pipes, each 2,600 feet long, laid in the bed of the Grand and across the Arkansas, convey the water to the pumping station. Low-lift pumps raise the water to a three-million-gallon settling basin. The water is then pumped through a 24-inch main, 20,800 feet long, to the city. A standpipe located in the northern part of the city, equalizes the pressure in the town.

The improvements to the water system are the result of recommendations made by the writer, who, in the fall of 1910, was retained by the city to investigate the existing water and sewerage systems, and to devise methods and means to adapt the existing systems, then overtaxed, to the present and probable future needs of the city. The improvements consist of the replacing of the two 16-inch suction lines by a 4-ft. 6-in. intake constructed in rock tunnel, with an intake tower at the upper end; the installation of additional high and low-lift pumping units; the construction of a water purification plant, including a six-million-gallon settling basin; the construction of the six-million-gallon reservoir with which this article deals; together with the construction of a 24-inch supply main, 12,600 feet long, connecting the reservoir located on the other side of the city from the pumping station with the existing distribution system.

The Need of a Large Storage Reservoir.—The object in constructing the reservoir was twofold; namely, to increase the pressure throughout the town, and to have at all times a large quantity of water available at a sufficently high elevation to maintain the pressure in the town at times of heavy draft or in case of a serious breakdown of the pumping station or force line.

The pressure in the central portion of the city ranges from sixty to seventy pounds. At times of heavy draft, these pressures cannot be maintained. A stand-pipe, 25 feet in diameter and 120 feet high, was erected in 1903 to help maintain the pressure in the city. The effect of the stand-pipe in this direction, however, is very slight, because of the small quantity of water in the pipe at the height at which it is required.

Conditions Which Influenced Design of Reservoir.—A storage and distribution reservoir, to be effective, should always be located as close to the city as possible; otherwise, too great a fluctuation in pressure will exist in

* Before the Convention of the American Waterworks Association, Minneapolis, June 25, 1913.

the distribution system. A site suitable for a reservoir exists within the city limits. In the northern part of the city, there is a knoll which reaches an elevation of 653 feet above mean sea level. The stand-pipe was erected on this knoll when the plant was built. In the extreme western end of the city is another knoll, known as Agency Hill, which reaches an elevation of 760 feet, thirteen feet lower than the highest water level in the standpipe. The top of this knoll has a hog-back shape, and averages about 200 feet in width. This is the only hill available for the construction of a distribution reservoir of the size required.

Good waterworks practice would require a city of the size of Muskogee to maintain a fire pressure of at least seventy-five pounds. A reservoir with its average water level at the elevation of the surface of the ground on the hill, viz., 760 feet, would give a static pressure of only

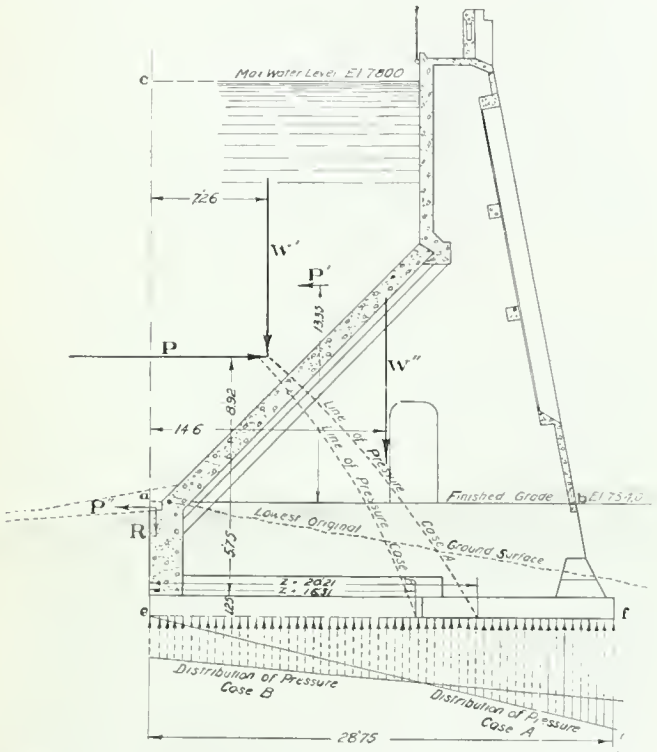

Fig. 1.—Section of Dam, Showing Diagram of Forces.

69.4 pounds over the central portion of the city. It was decided to adopt some type of construction that would insure a normal water level in the reservoir at least 20 feet above the surface.

The shape of the top of the hill, the size of the reservoir, the necessity of having most of the water stored above the ground, all tend to make the structure one of more than usual interest.

The top of the hill consists of three or four feet of clay and scattered boulder, underlaid with layers of clay and shale.

Reinforced concrete is practically the only material that could be used to construct a reservoir of the proportion and shape required by the conditions assumed above.

Possible Types of Construction.—A circular shape was decided upon. This shape is usually the most economical, but under the existing conditions, unquestionably so.

To obtain the required capacity of 6,000,000 gallons, a circular tank with its diameter limited to 200 feet requires a depth of 26 feet. To construct a circular tank of these dimensions in which the internal pressure is resisted by the tension in the shell, was considered inadvisable; first, because of the high cost of construction, and second, because of the probability of structural defects developing at the junction of the shell and the bottom. Such defects might permanently impair the value of such a structure as a reservoir.

A circular reservoir 200 feet in diameter will, when filled with water, expand 0.96 inches, on the assumption that the steel in the shell is stressed to 12,000 pounds per square inch. This enlarging of the cylindrical shell, as it affects its connection to the bottom of the tank, can be taken care of in one of several ways, all of which are more or less unsatisfactory:

First. By rigidly connecting the bottom to the side and making the bottom a thin section not more than 6 inches thick and sufficiently reinforced with steel so that it can stretch this amount without producing cracks large enough to allow the water to escape.

Second. By the use of a water-tight expansion joint at the point where the bottom joins the shell.

Third. By preventing the expansion at the bottom of the shell.

The third method calls for heavy, massive construction, is correspondingly costly, and is not successful unless the lower portion of the tank is designed with the greatest of care. When this is done, the economy of this type of construction no longer obtains, as the stress in the circular reinforcement depends on the expansion of the shell, which, if prevented by a rigid connection at the bottom, will reduce the working tension in the circumferential bars directly proportional to the amount by which the expansion of the shell is prevented.

As all of the methods mentioned for overcoming the weakness at the connection of the bottom to the cylindrical shell, are more or less experimental in a large reservoir, the writer was opposed to this type of construction. The amount of circumferential steel reinforcement required in the circular type, also increases with the square of the diameter. Therefore, the economy in the cost of construction found in the smaller tanks, no longer obtains in the larger sizes.

Another type of construction for the side walls of large reinforced concrete tanks is the cantilever section. This type of construction is not, it is believed, adapted to tanks deeper than 15 feet. In a tank of this type there is always the possibility of hydrostatic pressure developing under the broad base, thereby endangering the stability of the structure.

A third method, and one which has been in general use, is that in which the side walls are supported by buttresses or counterforts. This method of supporting the wall sections is a very economic one for tanks of considerable size in which the depth exceeds 8 to 10 feet. A modified type of this construction, in which the deck is inclined and supported by buttresses, is a very economic one for tanks of greater depth and is the one adopted for the Agency Hill reservoir described in this paper. The latter type of construction is not adapted to rectangular tanks of considerable depths. In rectangular construction, the corners are very apt to give trouble. Here, the pressures are at right angles to each other, and with the resultant deflections which are appreciable at the top of the tank, also as right angles, it is almost impossible to prevent large cracks from forming at the corners. These cracks are apt to be of such magnitude as to render the structure of little value as a reservoir. This criticism does not hold good when circular or elliptical construction is resorted to.

Description.—The reservoir as built is circular in form, 200 feet in diameter on the inside, and 31 feet deep in the centre. The walls of the tank are supported by fifty buttresses, radially spaced. The deck is carried straight between the buttresses, thus the reservoir is not truly circular but a fifty-sided polygon. For a distance of 10 feet below the water level, the sides are carried down straight; below this point, the sides are inclined at an angle of 45°. The bottom of the reservoir is a segment of a sphere, with a maximum ordinate of 5 feet at the centre.

The shape adopted is one in which practically all of the available water is stored above the surface of the ground. Of the total storage, amounting to 6,000,000 gallons, only 580,000 gallons, or 9.7 per cent. of the total storage, is below the finished grade, and approximately 40 per cent. is stored in the upper 10 feet, thus making it a very effective pressure-equalizing reservoir.

Fig. 1 shows the stresses acting on a portion of the dam subtending an angle of 7° 12′ at the centre, all of which is supported by one buttress. In this figure are shown all of the forces acting on the section.

The horizontal component "P" of the water pressure acts radially outward and amounts to 244,880 lbs. Its line of action is 8.92 feet above the line a-b (Fig. 1). The total weight of the water—W′—resting on the inclined deck is 218,560 lbs. with its line of action 7.26 feet to the right of the line a-c. The prismoidal form of the body of water resting on the inclined deck makes the computations, both for the amount of these pressures and their locations, somewhat involved, and for this reason they are not reproduced in this paper.

The weight of the concrete section—W″—based on 145 lbs. per cubic foot of concrete, amounts to 191,000 lbs. Its centre of gravity is 14.6 feet from the line a-c.

As several intermediate factors enter into the computations necessary to determine the line of pressure in the buttress and the distribution of the foundation pressure over the footing course of each buttress, it was deemed best to compute the limiting values of these pressures under the following assumptions:

Case A.—Based on the assumption that each section must stand independent of its neighbor.

Case B.—Based on the assumption that the various sections are united into a monolithic structure and that all the forces resulting therefrom are taken into account to the full extent that they may be counted upon to develop in the structure.

Case A.—The point where the resultant pierces the base, e-f, under this assumption can be obtained by taking moments about the point "e," as follows:

$$P\ (= 244{,}880) \times (8.92 + 5.75 + 1.25) = 3{,}898{,}490$$
$$W'\ (= 218{,}560) \times 7.26 = 1{,}586{,}700$$
$$W''\ (= 191{,}000) \times 14.60 = 2{,}788{,}600$$
$$\Sigma M = 8{,}273{,}790$$

$$z = \frac{\Sigma M}{W' + W''} = \frac{8{,}273{,}790}{409{,}560} = 20.21$$

"z" is the distance from the line e-a to the point where the resultant pressure on the foundation pierces the base.

The total width of the base is 28.75 ft. Therefore, the line of pressure falls 1.13 ft. outside of the middle third, thus making it appear that there will be considerable uplift at the heel of the buttress. This, however, is not the case. The total supporting area amounts to 117.65 sq. ft. Under the assumptions of Case A, the maximum pressure at the toe would amount to 6,727 lbs. per square foot, and the minimum to 29 lbs. per square foot. There is no uplift whatever at the heel. If, instead of a spread footing, a rectangular-shaped footing of the same area were used, the maximum pressure in the footing would be 7,755 lbs. per square foot, and the minimum, a tension of 795 lbs. per square foot.

Case B.—The line of pressure determined under Case A will not be the true line of pressure in the complete structure. In the complete structure a number of forces are developed, all of which add to the stability. The effect of these on the stability of the structure will be taken up in detail.

Effect of Bottom Connection.—Prior to placing the concrete in the bottom of the reservoir, further study of the problem indicated a probable weakness in the design of allowing the 6-in. bottom slab to span the refilled excavation made necessary in building the cut-off wall between buttresses. The plans of the bottom, therefore, were revised as follows:

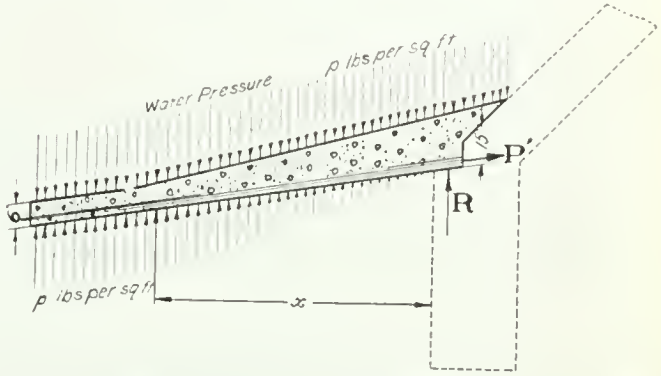

Fig. 2.—Connections at Base, Showing Acting Forces.

To strengthen the structure, the reinforced concrete bottom rests upon and is tied into the face slab by steel reinforcement. The concrete bottom is 6 inches thick and is reinforced wih ⅜-in. bars spaced 12-inch centres. Seven feet from the wall, the thickness of the concrete bottom was gradually increased from 6 ins. to a depth of 15 ins. directly over the supporting wall. The reinforcement in the bottom immediately adjacent to the wall consists of ⅜-in. square bars spaced 6 inches at the perimeter. The bottom is tied into the deck by half-inch bars, 5 feet long, spaced 12-inch centres.

Fig. 2 shows the connection of the bottom to the sides. In this figure are shown all of the forces that act on the section A, viz., the weight of the water resting on the bottom with an intensity of "p" pounds per square foot, the supporting pressure of the foundation increasing from zero at the support to a maximum of "p" pounds per square foot, "x" feet distant from the support; R, the reaction per lineal foot of the supporting wall, and P′, the pull per lineal foot exerted by the side walls. This construction would add appreciably to the stability of the buttresses in transferring the line of pressure nearer to the centre of the wall.

In Fig. 2 the distance "x" is limited by the strength of the bottom slab. Assuming a fibre stress of 20,000 pounds per square inch as the limiting stress that can be developed in the steel without permanently impairing the strength of the structure, we obtain a value of 6.28 ft. for x and a value of 3,400 pounds for R. The force T is developed in the ½-in. bars spaced 12-inch centres along the perimeter of the bottom and can reach 5,000 pounds per lineal foot without injury to the structure.

A new city engineer was appointed about this time, who was placed in actual charge of the construction. He was wholly out of sympathy with all the writer's plans.

The need of some additional reinforcement of the bottom at this weak point of connection was apparent when pointed out. As a substitute therefor, all the excavated material disturbed by the construction of the toe of the deck slab was removed and the space filled with plain concrete and the original thickness of the bottom maintained. This not only required more concrete, but it effectually destroyed the function of the drain laid at the foot of the wall to prevent hydrostatic pressure from developing under the structure. The opinion of the writer was not asked upon the wisdom of this change.

Effect of Continuity of Circumferential Reinforcement on the Stability of the Structure.—The circumferential reinforcement of the structure consists of sixty-five ¾-in. bars, eleven ½-in. bars, and six ⅜-in. bars, giving a total cross-section of 39.97 square inches. All of this reinforcement is lapped sufficiently at all connections so that the steel reinforcement of the shell can be considered to be practically continuous. As the shell expands under the internal pressure, this steel reinforcement is subjected to tension, thereby resisting directly a certain amount of internal pressure. The writer has every reason to believe that the diameter of the tank when filled with water will increase by ½ to 1 inch at the top. This expansion of the tank under pressure produces a stress of from 6,250 to 12,500 pounds per square inch in the circumferential steel reinforcement.

Assuming the average stress in the ring tension due to the circumferential reinforcement to be 6,000 pounds and to increase from 3,000 pounds at the bottom to 9,000 pounds at the top, the total outward pressure per lineal foot of tank thus resisted by the steel, amounts to 2,585 pounds. This is obtained from the formula,

$$T = pr$$

where T = ring tension = 6,000 × 39.97 = 239,820 lbs.
p = total hydrostatic pressure per lin. ft. of perimeter resisted by ring tension.
r = radius of tank, 92.75 ft. measured at the same height as the resultant line of action of the horizontal water pressure.

The height at which the force "p" acts can only be approximately determined. The centre of gravity of the steel reinforcement is 11.5 ft. above the line a-b and with the assumption as to the distribution of the pressure, the line of action of "p" is about 13.35 ft. above the line a-b.

In Fig. 1 are shown all of the forces acting on a portion of the dam, supported by one buttress, when this section is considered to form a part of the complete structure. The additional forces acting on the section, due to the rigid connections, are P′, R and P″.

P″ represents the radial tension that may be developed by the steel reinforcement connecting the bottom with the inclined deck. The value of P″ may reach 5,000 lbs. per lineal foot, or 52,900 lbs. per buttress, without injury to the structure.

R represents the reaction of the bottom on the supporting wall. This may also attain 3,400 lbs. per lineal foot or 35,900 lbs. per buttress.

The pressure—P′—under the assumptions made, amounts to a maximum of 2,585 lbs. per lineal foot of circumference, or 31,600 lbs. per buttress.

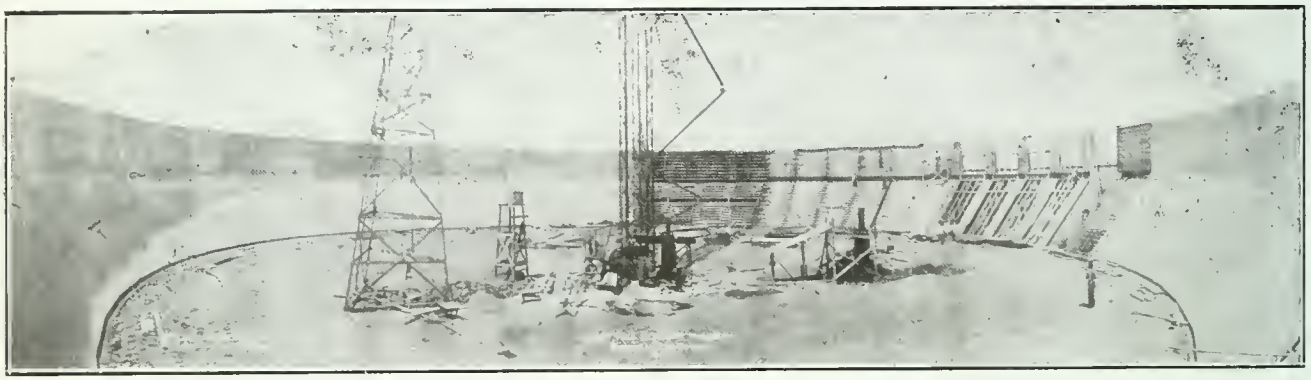

Fig. 3.—Interior of Reservoir During Construction.

Taking moments about the point "e" of all the forces acting on the section, under Case B we have:

P = 244,880 × 15.92	+ 3,898,490	
W′ = 218,560 × 7.26	+ 1,586,700	
W″ = 191,000 × 14.60	+ 2,788,600	
P′ = 31,600 × 20.35		— 643,060
P″ = 52,900 × 7.00		— 370,300
	+ 8,273,790	— 1,013,360
	— 1,013,360	

$$\Sigma M' = 7{,}260{,}430 \text{ ft. lbs.}$$
$$\Sigma V' = W' + W'' + R = 445{,}460$$
$$z = \frac{\Sigma M}{\Sigma V} = 16.31$$

Under Case B, the pressure line cuts the base 16.31 feet from the heel, well within the middle third. This gives a foundation pressure ranging from 4,962 to 2,544 pounds per square foot.

The foregoing computations show that the pressure at the toe of the buttress footing may range from 4,962 to 6,727 pounds, and the minimum pressure at the heel from 29 to 2,544 pounds. These pressures are conservative for the character of the foundation upon which the footings are placed.

The buttresses, which are radially spaced, are 15 inches in thickness. At the point where the inclined deck starts, there is considerable tension on the side of the buttress nearest the water. This tension is taken up by three ⅞-inch square bars at a unit stress in the steel of 9,000 lbs. per square inch, making full allowance for the

weight of the section; ignoring this, the stress in the steel will be 15,000 lbs. per square inch. Two ⅞-inch square bars are carried up along the face of the incline of the buttress to take care of any possible tensile stresses, especially at the upper end of the incline where these stresses may be considerable.

The face of the buttress upon which the deck rests, is corbeled out to 30 inches. The corbel is reinforced by two ⅝-inch square bars tied together by ⅜ square ties spaced 12 inches centres. These ties serve both the purpose of reinforcing the corbel against cantilever action developed by the deck resting on the outer ends of the corbel and preventing the splitting of the buttresses.

When the structure was about half completed, the writer discovered an error that had crept into the plans which called for ⅜-inch square bars in the spread footings of the buttresses in place of ¾-inch square bars as required by the computations. The footings as constructed do not give, in the opinion of the writer, a sufficient factor of safety in adequately distributing the pressure over the area assumed in the design, and it was therefore deemed highly advisable to reinforce the spread footings.

The method suggested for reinforcing the footings required the cutting out of a section of each buttress already constructed, and placing upon the footing a reinforced concrete beam 3 feet wide on the base and about 27 inches deep under the buttress and 12 inches deep at its outer end. This beam was to be reinforced with six ¾-inch square bars.

To obtain a good bond between the old buttress and the new work, it was proposed to maintain a head on the semi-liquid concrete so as to force it into the buttress and to maintain this head until the new concrete had obtained its final set.

It is regrettable that the city officials failed to appreciate the importance of strengthening the footings, which could have been done at a nominal cost and would not have added more than one per cent. to the total cost of the structure. In thus refusing to comply with the plans, they have assumed all responsibility for the structure. Although it is strong enough as built to withstand all the pressures that may come upon it, there is always a possibility that one of the buttresses may settle sufficiently to impair the usefulness of the structure as a reservoir. The cost of repairing this defect may exceed many times the cost of reinforcing the footings in accordance with the plans. Had the suggestion been carried out, it would have effectively reinforced the spread footing so as to enable it to properly distribute the pressure over the foundation.

Construction of Deck.—The deck, with the exception of the top, is not tied into the face of the buttress by steel reinforcement. The vertical portion of the deck is 10 inches thick. The thickness of the inclined portion varies from 12 inches at the top to 15 inches at the bottom. The steel reinforcement is stressed to an average of 5,200 pounds per square inch in the vertical portion of the deck, and to 10,000 pounds in the lower or inclined portion. The deck of the reservoir is constructed as a monolith; no expansion joints are used. This type of construction throws additional tension upon slab reinforcement, especially in its upper portion. Provision has been made, in the design, for this additional stress by using a somewhat lower working tension in the slab reinforcement than is otherwise necessary. A widening of the diameter of the tank at the top, of as much as an inch, will increase the stress in the circumferential reinforcement to 17,200 lbs. per square inch.

Fig. 4.—Nearing Completion, Exterior View.

Attention is called to the connection of the inclined to the straight portion of the deck. This joint, which is naturally a weak one, has also been made a construction joint. It has been strengthened by a 12-inch by 16-inch concrete beam reinforced with four ¾-inch square bars.

Hydrostatic Uplift.—In this article, no mention whatever has thus far been made of the possibility of hydrostatic pressure developing either under the concrete bottom or against the curtain wall, and thereby affecting the stability of the structure. This is guarded against by underdraining the spherical bottom with four and six-inch tile drains. Five 4-inch lines of drains are laid radially and drain to a sump at the centre of the reservoir. From this point a 6-inch drain is carried radially outward to a free outlet on the hillside. A circular line of 4-inch tile drain is laid entirely around the outer edge of the spherical bottom just above the footing of the 24-inch circular cut-off wall.

With these provisions, it is almost impossible to conceive of hydrostatic pressure developing to an extent to make it necessary to take it into consideration in the stress analyses. Under the worst possible conditions, with all the underdrains clogged, the hydrostatic uplift is limited to the bottom of the reservoir and the footing of the 24-inch wall, and even then the effect of it on the stability of the structure is negligible.

Architectural Treatment.—The city bought the property immediately adjacent to the reservoir to convert it into a park. To improve the appearance of the structure, the buttresses are widened out to three feet at the back, and between them a concrete curtain wall, four inches thick, is carried up for a distance of four feet above the finished grade. Between the tops of the buttresses, concrete arches are sprung. Each arch has a rise of three feet and a clear span of three feet less than the distance between the buttresses. The recess thus formed is filled at a depth of 12 inches with a thin curtain wall of stucco placed on hy-rib. At intervals of 5 ft. 7 ins., the hy-rib is supported by reinforced concrete beams. A concrete walk, 2 ft. 8 ins. wide, extends entirely around the reservoir. On the outside of the walk, a concrete railing in conformity with the architectural treatment of the reservoir is built. The false construction just described gives the reservoir a pleasing appearance of massiveness.

A driveway, 33 ft. 6 ins. over all, extends entirely around the reservoir.

Piping and Drains.—The water enters the reservoir through a 24-inch line. The outlet is located at the centre of the reservoir and is of the same size. Circulation is maintained by two check valves, one in the inlet and the other in the outlet, so arranged that the direction of the flow in these pipes cannot be reversed.

The overflow is located 18 inches below the top of the tank. The overflow pipe is 10 inches in diameter. A 10-inch cast iron pipe with its inlet in the lowest part of the spherical bottom and its outlet on the hillside, drains the reservoir.

Monolithic Construction.—Some question may be raised as to the economy of constructing a reservoir of the size described without expansion joints. The principal advantage that can be gained by monolithic construction is a general increase in strength. In a large structure, this increase in strength is by no means as great as a casual inspection leads one to believe. It is obtained only at a sacrifice. The stresses in the deck, when built continuous, are no longer static determinate quantities, and their amounts cannot be ascertained with any degree of accuracy. The stresses developed in the deck acting as a beam are also increased a more or less indeterminate amount by the expansion of the shell under pressure. For these reasons, comparatively low unit stresses must be used in designing the deck. The gain in strength due to continuity of deck construction, practically decreases as the square of the diameter in a structure of the type described. The increase in strength due to continuity of deck construction in large tanks is therefore very small.

Watertightness of the Structure.—Under ordinary conditions, the writer is opposed to the use of waterproofing ingredients or waterproofing applications, as both add considerably to the cost of concrete work. It is far better to put the value of the waterproofing materials into the concrete work itself by adding more cement. In general, the use of waterproofing ingredients or application tends to poor construction work, the contractor counting upon the waterproofing to materially help out careless construction.

The only waterproofing called for in the specifications under which the reservoir was constructed, was two coats of neat cement wash to be applied with a whitewash brush on the inside of the basin. The second coat must be applied before the first one has had time to get very hard.

Before the final acceptance of the work, the contractor is called upon to render the structure watertight if leakage develops in the basin in excess of five gallons per minute. The reservoir has been filled for a number of months to within ten feet of the top, and the leakage, as measured at the outlet of the underdrains, at no time has exceeded half a gallon per minute. No leakage whatever is visible on the outside of the shell.

Horizontal construction joints are used freely. The unfinished surface of these was always left in as rough a condition as possible, but was never roughened up after the concrete had partially set. The writer's experience has been that this roughening often loosens the stones in the partially set concrete, but not sufficiently so that the loose stones can be removed by brushes, a condition which is apt to impair the watertightness of the structure.

To start a day's work, the old concrete surface was thoroughly cleaned with wire brushes and water, and a semi-liquid mortar mixed in the same proportions as the mortar in the concrete was poured over the old work to a depth of half an inch. This method has given good, watertight horizontal construction joints.

Vertical construction joints were permitted only over the buttresses as such joints are very difficult to make watertight.

Cost of the Structure.—The following is an approximate estimate of the materials required for the structure, together with the contract unit prices:—

7,271 cu. yds. excavation, including grading, @ $0.55	$ 3,999.05
100 cu. yds. rock excavation @ $1.70	1,700.00
965 cu. yds. 1:2:4 concrete masonry @ $9.00	8,685.00
1,739 cu. yds. 1:3:6 concrete masonry @ $7	12,173.00
3,400 bbls. cement @ $1.50	5,100.00
189,900 lbs. steel reinforcement @ $0.0425	8,070.75
650 lin. ft. parapet wall @ $1.40	910.00
196 lin. ft. 24-in. cast iron pipe @ $5.40	1,058.40
215 lin. ft. 10-in. cast iron pipe @ $2.00	430.00
110 lin. ft. 3-in. cast iron pipe, drain, @ $0.50	55.00
12,300 lbs. cast iron specials @ $0.05	615.00
Two 24-in. check valves @ $200.00	400.00
One 24-in. gate valve @ $240.00	240.00
One 10-in. gate valve @ $25.00	25.00
880 lin. ft. 4-in tile-drain @ $0.12	105.00
160 lin. ft. 6-in. tile-drain @ $0.20	32.00
90 lin. ft. 12-in. vitrified pipe @ $0.70	63.00
One strainer 24-in. outlet pipe @ $7.50	7.50
630 lin. ft. 1-in. pipe railing @ $0.40	252.00
500 lbs. wrought iron @ $0.05	25.00
20,300 sq. ft. of stucco on hy-rib @ $0.15	3,045.00
Total contract price	$46,991.30

The reservoir was built on the summit of a hill about a mile from the nearest railroad station. All water used for concreting had to be carted up the hill, a distance of about a mile.

The final estimate exceeded the bid price by a very small percentage. The contractor's profit on the work approximated twenty per cent., indicating a reasonably economic reservoir, yet one which presents a very attractive appearance.

THE PENETRATION METHOD IN MACADAM ROAD CONSTRUCTION

By W. W. Crosby, C.E.,
Chief Engineer to the Maryland Geological Survey.

IN last issue of *The Canadian Engineer* a paper by Prof. A. H. Blanchard, dealing with the progress that has been made in America during the past three years, in bituminous paving by the mixing method was given. In connection with it, should appear a paper by Major W. W. Crosby, consulting engineer, Baltimore, Md., on the essential points of modern practice in America in the construction in open country of macadamized roads, bound with tarry, bituminous, or asphaltic materials, by the penetration or grouting method. The following is a crystalization of Major Crosby's paper, as read at the Third International Roads Congress in London:

Foundation and Drainage.—The necessity for firmer and stronger foundations, and, to this end, for the best possible sub-drainage, seems to be fairly widely and generally accepted, especially by those whose vision into the future is keen enough to permit them to recognize the probable increase in the demands on the foundations, to be brought about by better surfaces and by the consequent growth in both the amount and weight of traffic as well as in its severity. This necessity is even more apparent when the penetration method of constructing the crust is used because of the fact that such a crust appears to have frequently less inherent rigidity than many built by the mixing method.

Sizes and Shapes of Broken Stone for Bituminous Bound Surface Crusts.—While the mixing method may require a combination of different sizes of broken stone for the best results, with the penetration or grouting method under discussion, this is not the case. The unscreened product of a crusher is often used quite satisfactorily for the bottom course of the crust, though this course is frequently just as satisfactorily built of the coarser portions of this product. The choice depends on local conditions. It is considered inadvisable, however, to allow any particles over 3 ins. in length in this course.

In the second or wearing course, it is the best practice to pay considerably more attention to the screening and sizing of the stone particles. Very good results have been obtained by the use for the second course of cleanly screened stone passing a 1¾-in. round opening and not able to pass a ¾-in. Apparently better results have been secured by the use of pieces passing a 2-in. and retained on a 1-in. screen, and very good results seem to have been secured, where the pieces were most cubical, by the use of stone passing a 3-in., and retained on a 2-in. screen. More uniformity of grouting, together with longer wear, seems to be secured by the use of the larger sizes, and, further, a surface built of the larger sizes seems better able to withstand without damage the crushing strains of the heaviest loads carried on hard tires.

It has not been the best practice to permit too great a difference between the sizes of the screens used for separating the material for this course, about 1 in. being the customary difference in diameters of holes and 1½ ins., the maximum. A great difference seems to contribute toward lack in that much to be desired uniformity of grouting and this is especially noticeable in stone breaking into scaly pieces.

The writer believes that with a fairly cubical broken stone the best results have been obtained by the use of screens 2½ ins. and 1½ ins. in diameter of openings and that in the case of shaley rock 2 ins. and 1 in. have given the best results.

Reference has been made to "cubical" and "scaly" or "shaley" stone. There is general agreement that stones breaking cubically, without glassy fracture—that is, with fairly rough surfaces—and with sharp angles are most desirable.

The Use of Partially Worn Materials in Bituminous Bound Surface Crusts.—From the foregoing it will be seen that partially worn materials are usable for the bottom course of the crust, and they are frequently so used. Experience shows that such use should be accompanied by proper regard for the segregation, by harrowing or screening, of the fine material and detritus generally present with the coarser sizes. But the use of even the carefully separated coarser sizes of the old worn material is not generally permitted for the upper course of the crust as it is considered dangerous to successful results.

Thickness and Composition of the Strength Crust and of the Super or Wearing Crust Under Different Conditions.—So much depends on the particular conditions of the individual case that a general statement on this point is, with difficulty, made of any value. In addition to what has already been stated regarding sizes and shapes of the pieces of stone, it may be further said that the bottom course varies from a minimum thickness of perhaps 2 ins. to a maximum of 8 ins., measured after compaction. The average is probably from 4 to 5 ins.

This course is built both with and without the addition or presence of fine material (passing a ¾-in. or ½-in. screen) as local conditions seem to determine though it seems that the proper use of a moderate amount of the smaller material generally produces a firmer and stronger first course.

Occasionally the completed bottom course has been given a coat of pitch before spreading the upper course stone, but ordinarily this use of the pitch is not followed, nor does it generally seem to be considered necessary to endeavor to secure any penetration of the pitch to the bottom course through the upper course stones.

The super or wearing course, it may be said, is generally from 2 to 3 ins. in thickness after rolling. For the proper penetration and adherence of the bituminous material or pitch of whatever nature, it is now generally agreed that the particles of stone must be clean and free from coats of stone-flour, dirt or dust. Apparently a general preference exists that they should also be dry but there is still much discussion on this latter point, and it is by no means determined what lack of dryness can be permitted without detriment to the results. A very few have even advocated the presence of a certain amount of moisture on the stone before the application of the pitch, but the writer prefers a dry condition, though he agrees that, in most cases, a moderate amount of moisture is not as objectionable as dirtiness or dustiness.

Another most important factor affecting both the courses of a bituminous as well as of a water-bound road crust is the sufficiency of the rolling given them. So generally is it now accepted that with water-bound macadam the utmost possible compaction and interlocking of the stone by rolling is necessary for first-class results, that the truth of the saying that "Rolling is the life of the road" is everywhere recognized. With bituminous macadam built by the penetration method, the concordance on this point seems to be as yet less complete. Some road-builders actually insist on a minimum of rolling before the application of the pitch and others do not require a maximum. With the writer's work, however, there is

no question but that the quality of the results has been in direct proportion to the amount of compaction or interlocking secured by proper rolling, and it is his opinion that results generally show that the proper rolling of the stone before the application of the pitch is of the greatest importance.

Relative Advantages and Use of Tar, Tarry Compounds, Asphalt, Bitumen and Other Materials.—The proper selection of the bituminous material or pitch for use under the penetration or under any method is a most serious one and is influenced by many conditions other than method of use. Such, like price, soil, weather and traffic conditions, desires of users of, and abuttors on the road, the conditions likely to prevail regarding after-maintenance and cleaning, etc., etc., are largely local, and are probably not germane to the discussion in this paper.

Confining the statements to the above subjects and considering only the penetration method of use, it may be said:

The use of unrefined tars has been found unsatisfactory and has been practically abandoned. The extent and character of the refining seems to depend largely on the peculiar conditions to be expected in any case of the use of the material, but some points in this connection are still unsettled. It seems generally agreed that the presence in the tar of more than a minimum of water or ammoniacal liquor renders it undesirable for this method of use; that certain amounts of "light oils" are necessary for giving to the pitch the desired fluidity in handling; that a generous proportion of "middle" and "heavy" oils —especially the latter—is demanded in order that the tar may retain the longest possible "life" or elasticity after use and under the ageing or weathering effects of weather and traffic as well as for giving the "body" to the pitch demanded by this method; and that a limited amount of "free carbon" may be advisable in order to help to give body to the tar and to assist in reducing its susceptibility to changes in temperature. This "free carbon" (matter insoluble in carbon bisulphide) may be either the natural fraction of the tar or it may be added foreign material such as Portland cement or finely powdered limestone. Some crusts built by the penetration method with a low carbon tar have seemed to improve as fine material was supplied by traffic.

At first an opinion existed widely that the value of a tar for road work was in inverse proportion to its percentage of "free carbon" content, but the writer was loath to accept this view because of his knowledge of the proved great value of certain tars in which this fraction was unusually high. Results of practice with the penetration method to date seem to indicate that it is not the simple proportion of the "free carbon" fraction to the whole tar which was of use as a criterion in passing on the value of the tar for the penetration method but rather the ratio between the "free carbon" fraction and one or more other fractions (the heavier oils) on which depends the worth of the whole tar.

The use by the penetration method of tars with a "free carbon" content of less than 2 per cent. has resulted in an objectionable susceptibility of the road surface to summer heats, while the use of tars whose "free carbon" fraction was greater than the percentage of the heavier oils in the same tar has shown a too great hardness or friability under extreme cold.

In the use under the penetration method of the native asphaltic materials and of the oil residuums, a certain amount of "light oil" seems desirable for the sake of fluidity, and a limited amount of "middle" and "heavy" oil fractions for the sake of "life" and elasticity. The "pitch" fraction, being the base in those cases, must possess the desired characteristics of adhesiveness, cohesiveness, lack of brittleness and resilience. The proper proportions of the lighter fractions depend on the characteristics, in those particulars at least, of the "pitch" as well as upon the conditions of traffic, etc.

Early practice under the penetration method condemned the use of "cut back" products,—i.e., those artificially prepared by the addition of oils to previously reduced pitches—probably because in many cases such pitches had not been carefully prepared with this end in view but were by-products or wastes from processes arranged for the production from the raw material of the portions other than the pitch.

The writer believed that not only was it possible to make satisfactory road compounds for use under this method from a pitch by cutting it back with lighter materials, but also that it was quite possible that, in many cases, a far more satisfactory product could thus be obtained than by simple reduction, to the desired consistency, from the raw material.

Subsequent experience has seemed to confirm this theory and some of the most satisfactory results under the penetration method have been secured by the use of pitches compounded by adding the necessary oils to a previously and purposely prepared, fairly hard, asphaltic pitch.

In such cases, the harder pitch possessed all the usual qualities of a good asphaltic paving pitch and the flux, those of a proper flux for making asphaltic cement, except that perhaps more volatile oils were included to permit of easier and better use under the peculiarities of the penetration method. Experience seems to have proved that there is a limit to the amount of "greatness" that can safely be permitted in the flux so—as above—used and that an excess of this characteristic may ruin the results under this method by permitting, if not encouraging, the internal motion between the coarse particles of the crust, especially in the usual case of a deficiency of the smaller sizes.

In the use of the materials referred to, so much depends on the peculiarities of the local demands that brief general statements are again somewhat difficult. A few such may, however, be justified. For instance, experience has seemed to prove that in the use of tars or tar-compounds under the penetration method, better results have been secured where the softer materials have been used provided such softness was not secured by an excessive proportion of volatile or light oils. This seems especially true when considering the tendency of certain pitches to produce surfaces slippery in wet or cold weather.

As regards asphaltic materials (including oil residuum) it seems that in many cases where softness has been given by a generous amount of the middle oils (non-volatile) the resulting surfaces under this method have shifted under traffic in warm weather and evidenced "lubricating" rather than the necessary "binding" characteristics of the pitch compound.

Regarding the quantity of pitch to be used under the penetration method while the character of the wearing course (as to sizes, kind, etc., of the material) will affect the decision, it may be stated that ordinarily the successful amount of bituminous material per square yard of surface seems to have been between 1½ and 2 gals. The writer has built entirely satisfactory work with as low as 1¼ gals. per square yard, but under exceptional condi-

tions. He has also seen instances where as high as 4½ gals. per square yard of tar was used, but with little dissatisfaction with the resulting surface. In fact, the main objection that appeared in those latter cases came from some bleeding of the pitch over the road surface during the first summer after construction, and this was readily obviated by one or two additional coatings of stone chips.

It has been suggested that an excess of pitch in the crust, provided it is located well down in the latter, may be of some decided advantage in that it may furnish a reservoir from which additional life will be given to that pitch exposed on the surface to deterioration by traffic and weather. However, penetration of the pitch to the bottom of the larger sized stone in the surface seems ordinarily to be sufficient for success.

Practice has varied in the application of the pitch under the penetration method, some applying the bulk (say, ¾ of the total amount) at first and then, after spreading a coating of chips and rolling, applying the balance with another coat of chips and more rolling. Others apply all the pitch at once. The writer concludes from his observations and experience that the latter way generally gives more satisfactory results.

With the mixing method, where the quantity of pitch may be reduced to a minimum, certain conditions may render advisable a "flush coat" of pitch and chips. But "in open country" where even slight dustiness may not be objectionable and where slipperiness may be decidedly offensive, the omission of the flush coat is generally, under the penetration method, better because of the longer freedom from unnecessary smoothness. And the writer has not found that the omission of the flush coat has, where the road crust was properly built by this method, rendered the crust visibly more susceptible to the destructive effects of either horse-drawn vehicular or motor traffic.

It seems generally admitted that with the penetration method the use of a "flush coat" is mainly for "insurance," i.e., to overcome or make good any defects from previous poor workmanship or inequalities in the earlier processes.

Uniformity of grouting has been referred to as desirable, and is now generally so recognized. Toward this end as well as for the sake of economy, efforts have been made to supplant the early system of hand-pouring by some mechanical distribution of the pitch. Some very successful machines have been devised for the purpose and it seems generally agreed that the best results under the penetration method are secured by the use of such appliances distributing the pitch under pressure of from 20 to 70 lbs. per square inch.

Cost Data.—The usual variations in cost, resulting from different local conditions, have been omnipresent with the penetration as with any other method. However, it may be stated that with labor at 15 cents, single horse carts at 27½ cents, two-horse carts or wagons at 50 cents, foremen at 30 cents, per hour, stone at $1.75 ton delivered on the work, and pitch at from 7 cents to 10 cents per gallon delivered at a railway station within one mile of the work, the cost for building by the penetration method a pitch-bound macadam using from 1¼ to 2¼ gals. of pitch per square yard averages between 15 cents and 25 cents per square yard over and above the cost of building water-bound macadam under the same conditions. A decrease in this cost has quite steadily occurred and it seems may be looked for further as proficiency in practice and as mechanical appliances for the work are developed.

BUREAU OF MINES' BULLETIN ON EXPLOSIVES

"The Analysis of Black Powder and Dynamite" is the title of Bulletin No. 51 recently issued by the United States Bureau of Mines.

This bulletin outlines the methods of analysis that are used by the Bureau of Mines in the examination of certain classes of explosives. The present form of most of these methods has been worked out in the Bureau's explosives laboratory. The methods employed by Pro. C. E. Munroe were taken as a basis, and were elaborated to meet the demands incident to the treatment of complicated mixtures and to the development of the explosives art. A subsequent bulletin will discuss the methods of analysis of "permissible" explosives, many of the latter being of decidedly complicated character and requiring special treatment. This bulletin presents the methods of analysis of "Ordinary" dynamite, and the ammonia, gelatin, low-freezing, and granular dynamites, and the common grades of black gunpowder and black blasting powder. The bulletin is published by the Bureau for the information of all persons interested in explosives and their safe and efficient use in mining work.

As the term "ordinary" dynamite, though much used, has no conventional meaning, and may be used to cover a wide variety of compositions of matter, it may be noted that the standard dynamite used at the Pittsburgh testing station is a good example of the "ordinary" dynamite known in this country. This testing station dynamite has the following composition:—

Composition of Pittsburgh Testing Station Dynamite.

	Per cent.
Nitroglycerin	40
Sodium nitrate	44
Wood pulp	15
Calcium carbonate	1

As most permissible explosives contain only the constituents found generally in the various types of ordinary dynamite, the chemist will usually find it possible to analyze such explosives either wholly or partly by following the general methods of analysis here given for the type of explosive that seems most closely related to the one under examination. The methods of extraction with ether, with water, etc., outlined in the bulletin are general methods which are applied with equal success to all classes of explosives, and therefore by the use of these general methods, following a thorough qualitative examination, little difficulty should be met except with those classes of permissible explosives that contain large amounts of salts holding water of crystallization, such as alum and magnesium sulphate, or those containing an unusual number of uncommon constituents. Even with such explosives, however, if the information desired is principally in regard to the percentages of explosive ingredients (nitroglycerin, ammonium, nitrate, etc.), the methods outlined in this bulletin may be satisfactorily followed.

The Third International Congress of Refrigeration is to be held at Chicago in September next. It will be divided into six sections, dealing with: (a) Liquified gas and units; (b) the design, construction, operation, and method of testing refrigerating machinery and insulating materials; (c) the application of refrigeration to foods; (d) the use of refrigerating apparatus in the industrial arts; (e) refrigeration in railway and steamship transportation; (f) questions relating to legislation and administration. The secretary-general is Mr. J. F. Nickerson, 431 South Dearborn Street, Chicago. The first Congress was held in Paris in 1908, and the second in Vienna in 1910.

THIRD INTERNATIONAL ROAD CONGRESS, LONDON.

On the 23rd of June, at the invitation of the British Government, and under the patronage of His Majesty King George V., in Central Wesleyan Hall, Westminster, was convened the Third International Road Congress for the deliberation and discussion of matters relating to the world-wide movement for road reform.

That the movement is world-wide is shown by the fact that some 39 countries were officially represented and in all about 3,000 delegates attended. Canada was ably represented by Mr. W. A. McLean, engineer of highways for Ontario; H. S. Carpenter, superintendent of highways for Saskatchewan; W. G. Tretheway, of the York County Highway Commission, and others.*

That the meetings were destined to be eminently successful was evinced by the large number of men, of high rank in public affairs in their respective countries, who had assembled to give their experience in matters so vital to the interests of the community—the improvement of highways.

The opening meeting was presided over by the Right Hon. the Chancellor of the Exchequer D. Lloyd-George, who expressed his deep interest in and the sympathy of the government with the objects of the congress. For some years past there has been in Europe a distinct movement in road reform. This movement found expression in the formation in Paris in 1908 of the Permanent International Association of Road Congresses. At that meeting some 400 men, eminent in professional, scientific and administrative work, chiefly from France, Germany and Great Britain, assembled to discuss matters relating to the movement. This was followed by the Brussels Congress in 1910, at which about 1,000 delegates attended, and the impetus, largely given by the association, is shown in the extraordinary attendance at this, the third congress.

Since the second congress concluded its labors in Brussels the movement in favor of road reform has made immense strides, and the past three years have been a period of constant activity and improvement. The problem of treating roads with bituminous materials has been advanced from the experimental to the practical stage, and has now attained an assured position. Experience has proved that roads can be built of bituminous material which are not only practically dustless but are also capable of carrying the heaviest ordinary traffic.

The manner in which the programme was arranged and carried out in every detail reflects great credit upon the Organizing Committee and the chairman, Sir George S. Gibb. In dealing with a matter of such wide scope, very thorough and systematic arrangement becomes essential and the plan adopted in this instance was as follows:

The papers that were to be submitted were sent in some months previous to the meeting. These were placed in the hands of sub-sectional committees for criticism. The sub-committee reported on the salient features and added recommendations or resolutions. Thus, every paper came before the congress in a predigested form and the resolutions only were discussed. A glance at the following list of subjects of the programme will give some idea of the scope and import of the deliberations of the congress, and when it is considered that many papers were submitted in each case, an estimate can be made of the volume of pre-convention work performed by the committee.

The programme comprised the following:

1. Planning of Streets and Roads.
2. Types of Surfacing to be Adopted on Bridges, Viaducts, Etc.
3. Construction of Macadamized Roads Bound With Tarry, Bituminous or Asphaltic Materials.
4. Wood Paving.
5. Lighting of Public Highways and Vehicles.
6. Observations Noted Since 1908 as to the Various Causes of Wear and of Deterioration of Roadways.
7. Regulations for Fast and Slow Traffic on Roads.
8. Authorities in Charge of the Construction and Maintenance of Roads, Functions of Central Authorities and Local Authorities.
9. Finance of the Construction and Upkeep of Roads.

The exhibition connected with the congress was most interesting and instructive, especially the exhibit of the Road Board, in which many types of construction were shown by portions that had been taken from actual roads, a full description being given in each case. There was also an excellent display of materials, machinery and appliances.

The arrangements for road excursions were fully satisfactory. The writer had the opportunity of going over the Berkshire roads in company with the chief surveyor, and we found them in excellent condition, combining in a high degree all the essential qualities of a good road. The district is almost entirely agricultural, and the roads are subjected both to heavy traffic and that of fast-moving motor-driven vehicles, and meet all the requirements admirably well. There appears to be no reason why we, in the older parts of Canada at least, should not have roads that would meet our conditions as well as these do the conditions that obtain in England. One was most favorably impressed with the manner in which all points were discussed and the manifestly good spirit which prevailed throughout the entire congress. Men of high attainments and character unselfishly gave the best of their services in the promotion of one object, that of making the world a little better for having lived in it.

The impetus given to the movement will be difficult to measure, but one can feel assured that those from Canada will return fired with new zeal for the promotion of that upon which so much of our future depends—highway improvement.

A. T. LAING.

London, June 28th, 1913.

*[The University of Toronto was represented by the writer of this article and by Professors J. McGowan and P. Gillespie.—Ed.]

Some practical rules laid down by the American Foundrymen's Association for obtaining castings resistant to corrosion are as follows: (1) Use white iron if possible. (White irons are especially useful where any acidity is to be encountered.) (2) If not practicable to use white-iron castings, chill those surfaces which are to be in contact with corrosive conditions. (3) If grey iron must be used, get dense, close-grained castings through the use of steel scrap or otherwise. (4) Avoid oxidized metal; use pigirons of good quality, together with good cupola practice. If possible, use deoxidizing agents; for example, titanium or vanadium. (5) Keep the sulphur as low as possible.

THE INTER-ATTRITION THEORY OF ROAD WEAR.

At no time in its history has road building received such attention as the road associations are devoting to it this season. Certainly many discussions, long pending, should be settled and many points scientifically gained as a result. Highway construction and maintenance has sufficient technical knowledge now connected with it to prevent further profuse expenditure upon methods not the most suitable.

A theory gaining ground among road engineers in England, and which has to do with the wear of roads, attributes the chief destructive tendencies to an internal movement among the stones at some depth below the surface, producing an abrasion which results in a gradual rounding off of angles and corners and impairs their interlocking and resisting power. According to a Times' correspondent, the dustlessness of roads, especially if they are made with tarred material, and not merely tar painted on the surface, arises in a comparatively small degree from the fact that the surface is protected from wear. The real saving lies in the fact that between the stones, which are packed together in close association below the surface crust, there is little or no wear, owing to the oily nature of tar or bitumen as a binder, which prevents the faces of the broken stones from actually grinding against each other under rolling weights. The surface wear of an ordinary non-tarred road is, except in cases of heavy continuous traffic, a comparatively negligible factor, and it is undoubtedly heavy weights which are the chief cause of road wear seen above and unseen below the road crust. It thus comes about that the heavy traction engine, even though its tires may be broad and the diameter of its wheels large, from its mere weightiness, apart from any question of speed, causes irresistable crushing of the road surface and the inter-attrition of the stones beneath it. This produces more dust and more mud than the passage of thousands of smaller vehicles even though they may travel at a rapid speed; for light vehicles affect only the part of the road near the surface.

Ordinary tar-macadam or tarred slag, where slag from blast furnaces is used instead of stone, laid in a layer several inches and afterwards rolled, forms a homogeneous foundation for the surface crust, in which the stone probably forms about 75 per cent. of the total volume, and the combined material—that is, small, broken stone and tar, or some compound of it—forms the remaining 25 per cent. of it. When this is rolled together the inter-attrition of the stones is reduced to a minimum, for every angle of every stone is bound together firmly or is coated with an oily surface. The beneficial result extends far beneath the surface of the road itself; so that when these stones move, if they ever do, under the influence of heavy traffic, all that happens is that a certain proportion of superfluous tar or bitumen may be forced to the surface, and ordinary mud, such as is produced by the grinding together of two plain surfaces, does not appear.

Other forms of bituminous binding that meet this intersticial wear, and confine it largely to the upper surface of the road, include several patented surfacing preparations, to be applied to ordinary water-bound macadam road. Tar grouting, where the tar or bituminous mixture is poured upon freshly laid dry macadam immediately after laying and rolling, or a modification of it using standardized pitch, or a further modification, in which a layer of a fine mixture of tar and concrete is laid, and upon which dry macadam is spread and rolled, are

among the processes that are meeting with fair success.

At any rate, the advisability appears now to be practically demonstrated of laying down roads with bituminous material for a depth of several inches, rather than merely painting the surfaces with tar, and leaving the untarred stones underneath to grind against one another, inevitably producing mud and dust.

ENGINEERS AND LITERATURE.

The study of literature in connection with an engineering course is frequently quoted as being decidedly out of place. The fact remains that many young engineering graduates find the writing of intelligent, comprehensive reports upon the work which is in their charge to be one of the hardest problems with which they have to contend, likewise the most disliked and generally the least satisfactorily fulfilled of all their duties. The failing has often been attributed to engineers in general, until one is forced to admit that it is something with which the matter of training has to do and, therefore, which reflects upon the engineering course.

Against the contention that the study of literature is beyond the horizon of the engineering school are the opinions of a great majority of the older followers of the profession—men whose rank and affluence followed the cultivation of a breadth of reading, the necessity of which they recognized in their early problems. The subsequent study of literature brought them into the possession of a better working knowledge of engineering English, which soon reflected itself in what literary work their profession required of them.

To the engineer of to-day it does more. A study of literature means a study of men, of human character, of selection and adaptation, and ability to deal with men. A study of the writings of others enables him to write, furnishes him with more than a meagre share of a knowledge and appreciation of the best in literature, and enables him to converse, with intelligence and equality, with other cultured men in his and other professions. It broadens his scope of society and business, it means recreation, relaxation and inspiration to him. Finally, the most potent thinkers of the world are, one and all, students of literature. A study, then, that has so much to do with the establishment of a man's standing among his fellow-men, should have prominence in any educational course, and to few courses does it apply more materially than to the engineering course.

EDITORIAL COMMENT.

The American Waterworks Association, at its thirty-third convention, held recently in Minneapolis, announced a membership exceeding 1,000. A new constitution was adopted, its chief feature being provision for the establishment of local sections throughout the country. The convention in 1914 will be held in Philadelphia.

* * * *

The first official statement of the new manager of railways for the Dominion Government discloses the intention of creating a 6/10 grade on the Intercolonial, from Montreal to Halifax and Sydney. The change will be affected at the rate of about 100 miles per year, short lengths of the line having to be entirely rebuilt. This remedying of grades, which are in some instances excessively heavy, will greatly increase the effective hauling power of the I.C.R. locomotives.

Mr. Gutelius further announces the intention to double-track the Intercolonial. A section some thirteen miles in length, between Levis and Chaudiere will be completed this season, and other sections will follow. At present the line from Moncton to Pansac Junction and from Halifax to Windsor Junction is under double track.

* * * *

The world's greatest drydock, to provide accommodation at Levis, Que., for the largest ocean liners, is about to be constructed as the first of a series of drydocks and ship repair plants under contemplation by the Department of Public Works. Others will be located at Esquimalt and Vancouver on the Pacific and Sydney, St. John or Halifax on the Atlantic. The contract has just been awarded for the Levis drydock, the cost to approximate $2,600,000, construction to be commenced at once, and to be ready for use in 1915.

LETTERS TO THE EDITOR.

The Road Congress.

Sir,—The International Road Congress held last week in old London was about as cosmopolitan a gathering as one could hope to see anywhere. There were forty countries or states officially represented, and the list of delegates included the best, socially and professionally, that those countries could furnish. His Majesty the King was Patron. The list of honorary presidents included five of his Majesty's ministers. The presidents of six leading engineering societies of Great Britain were among the the vice-presidents, and served, with others, on the organizing committee. It may be of interest to remark that Germany and France were officially represented by the two largest delegations—men, in the main, whose official positions and scientific attainments would lend distinction to any gathering. The proceedings were carried on simultaneously in four different halls adjacent to Parliament and Great George Streets, within a stone's throw of the House of Commons and Westminster Abbey, and in a neighborhood rich in historic associations. The sectional meetings were conducted mainly in English. The remarks of those who contributed to the discussion were invariably abstracted and translated by interpreters for the benefit of those who understood only one language. Generally, the arrangements were satisfactory, and the few disappointments that did occur were usually due to contingencies very difficult to foresee and still more difficult to provide for.

An instructive exhibition of materials and appliances was in progress during the week. This included machinery for the preparation of materials and the construction of roads, proprietary, and other articles and samples of types of highway construction taken from actual roads. Each booth had its demonstrator, usually in frock coat and silk hat, who was gracious and courteous, but not offensively aggressive; who was tolerant of competitors, and who gave one the impression that he understated rather than overstated the merits of his goods. For the Britisher is thorough if he is anything, and depends on the excellence of his article first, and the fairness of his business methods second, to create a market for his products.

Of the actual road sections exhibited, probably none were of greater interest than those supplied by Mr. J. A. Brodie, city engineer of Liverpool. These had been cut from the streets of that city and some of them had seen many years of service. One of these, I recall, consisted of six-inch Welsh granite setts above a six-inch concrete base, the two being separated by two inches of sand filler. The joints between adjacent setts appeared to be filled with grout. This road, subjected to constant heavy traffic, had stood for 41 years and appeared to be still in good condition. Another, of somewhat similar type, except that the binder between the individual setts was asphaltic instead of grout, had stood quite well under what was reported as medium traffic since 1883. Other samples gave evidence of remarkable wear in treated wooden blocks. One section consisted of creosoted dial blocks on an 8-inch concrete base. The blocks appeared to have been originally separated from each other in rows by tiny horizontal wooden strips. This road was in fair condition and had been in service since 1893. But the most ancient of all was the Roman road, discovered in 1897 at Rochester. The construction was substantial beyond doubt, since below the seven-inch paved roadway were: gravel, 9 inches; small flints, 7 inches; chalk, 5 inches, and large flints, 42 inches. Below this, finally, were timber caps and piles, the highway having doubtless been constructed across a marsh. The aggregate depth, exclusive of the timber, was 70 inches. John Bull has undoubtedly some substantial prototypes for his guidance when he turns his attention to the building of highways.

Finally, let me point out, the International Road Congress affords to the observer, mainly by contrast, a view of some of the anomalies of present-day civilization. Mr. John Burns, presiding at the final banquet of the Congress, held at the Hotel Cecil, on Saturday evening, June 28th, in moving the toast to the "International Road Congress," asserted that to the modern road was due the wonderful diminution of infantile mortality and infantile diseases, and that the lack of roads and communications had led to estrangement, hostility and misunderstanding between nations. This great International Congress, composed of representatives of the sober thought of fifty nations, goes somewhat farther and shows how the constructive arts afford a common meeting ground, prevent misunderstanding and promote good-fellowship and international good-will. But this all happens in a week when the Imperial Chancellor of Germany is asking his Reichstag for six new cavalry regiments "for the protection and security of the Fatherland," when the French populace are being forced into universal military service, and when in England the First Lord of the Admiralty has announced that because of the action of the Canadian Senate in rejecting the naval bill, the construction of three dreadnoughts will be accelerated. It is interesting to observe that he too makes use of that hoary fiction, "the safety, not of our trade, but of our lives." Meanwhile, the innocent citizen is perplexed to understand whose concealed hand is working the puppets. That the better spirit of the land is in some degree becoming disgusted with the whole sordid business is evidenced by an incident that happened at Sheffield during the week. A large number of the Roads Congress delegates were the guests of the Hadfield Steel Manufacturing Company at that city on the occasion referred to, and had been given an actual demonstration of the power of the modern projectile in penetrating armor plate. Sir Robert Hadfield, head of the great firm, in addressing the gathering, remarked significantly on its cosmopolitan character, and hoped that when the Congress again met in England his firm would not be engaged in this kind of work. The anomaly of our present civilization is that while efforts looking toward the betterment of the race, its health, its comfort, its education and its happiness, were never more active than they are to-day, the perfection of engines for its destruction was never so complete.

PETER GILLESPIE.

London, July 3rd, 1913.

Long Distance Measuring With a Stadia.

Sir,—In traversing with a stadia it may seem incredible to some that distances of 3,000 to 4,000 feet are reported to be read or measured. Where precise measurement is required this is not possible at a single setting, but when fairly close approximations are sufficient, such long traverse sights are not infrequently taken. The method used may be of interest.

In these cases only half the wire interval is employed, that is, a 13-foot rod may be read over a distance of 2,600 feet. In some transits the two half wire intervals are not precisely the same, and in cases where the wires are attached, it is impossible to properly adjust them for this work unless they are sent to a repair shop for alteration.

In reading half the wire interval the centre wire is focused on the top of the rod, and the lower wire is marked on the rod with a target, at, for example, ten feet from the top, corresponding here to a distance of 2,000 feet. In such long distances it will, of course, be impossible to read the rod directly, and one must depend upon the rodman for its measurements. A target can easily be seen through the transit from a distance of 2,000 or 3,000 feet.

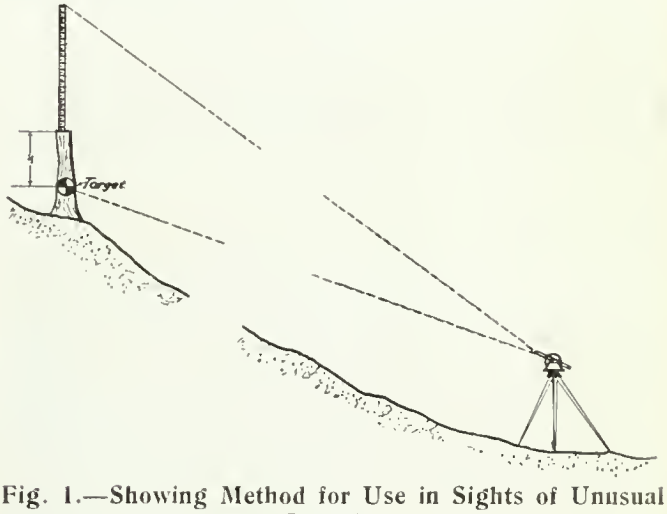

Fig. 1.—Showing Method for Use in Sights of Unusual Length.

The writer has taken many sights of this length in traversing lakes, no effort being made to read the rod, the position of the target only being viewed with the lower wire. As stated, the middle wire was focused upon the upper end of the rod and the reading was made downwards. Thus the target makes it much easier for the transit man, although its use is not required for shorter distances of, say, 500 to 600 feet.

The average 13-foot rod will read up to 2,600 feet in this way. When longer sights are required the accompanying illustration shows a convenient method to pursue.

The rod is held on the top of a tree stump as shown. It is sometimes necessary to cut a tree for the purpose of

securing a stump of sufficient length when longer distances are in use; for example, 3,500 feet or upwards. With the rod in this position the target, whatever it may be—a field book or a page of white paper—is read on some part of the stump. By this means the writer has taken sights of 4,000 feet on several occasions when absolutely necessary, as in the case of an intervening lake. The transit might be set up on one shore of the lake and a sight to the opposite shore might necessitate readings through such a distance. I have known sights of one mile in length to be taken on a lake. These are rare instances, however, and conditions must be suitable, for telescopes are few through which a target can be satisfactorily read at a distance of a mile. Extreme difficulty is experienced in focusing the wire upon it even at a distance of 4,000 feet, it being almost impossible to see the target unless a little ingenuity is used in distinctly outlining it.

Such long-distance sights, provided proper precautions are taken, have great advantages in traversing. One accomplishes more, and again, a single long-distance sight is more correct than two of short distances. The longer the sight the straighter the line. This is well exemplified in chain measuring where the transit man who strives to run a perfectly straight line knows the value of a single sight of, say, 2,400 feet in comparison with two sights of 1,200, or four sights of 600 feet each.

On land, of course, these distances are frequently impossible owing to divergencies of contour; but on the water and in some parts of the western provinces very long sights may sometimes be taken. In the case of the latter, however, level or open prairie work is no longer abundant, the major portion of the unsurveyed west being covered with bush and muskeg.

J. A. MACDONALD.

Ottawa, Ont., July 10th, 1913.

ADDITION TO THE TORONTO FILTRATION PLANT.

IN his report to the Board of Works relative to the proposed extensions to the waterworks system of the City of Toronto, Commissioner of Works R. C. Harris recommends the installation of a mechanical system of filtration to supplement the slow sand methods now in use at the Island.

This report is the first official announcement that has been made concerning the expenditure which the $6,000,000 by-law of January 1st, 1913, was intended to cover. During the past six months the Works Department has given the situation most careful study, and the scheme of extension now advocated is the result of a very thorough investigation. As intimated in the June 26th issue of *The Canadian Engineer*, the Commissioner of Works had decided it advisable to base his report upon the experience and careful investigation of the city's own engineering staff, rather than merely to accept the report of the board of experts appointed previous to his administration.

The new report in full is as follows:—

Gentlemen,—We beg to herewith submit report re addition to Island filtration plant.

There are two standard methods of filtration, viz., slow sand and mechanical, both of which are capable of giving equally effective results.

In the former system, the raw water, without chemical treatment, is passed through beds of sand and gravel at the rate of from three to five million gallons per acre per day, and the effluent is carried by gravity to a clear water reservoir, from which it flows to the distributing pumps.

In the mechanical system, the water is pumped from the source, and a coagulant, usually in the form of sulphate of alumina, is applied before entering a coagulating basin, where sedimentation takes place for several hours. The water is then passed through rapid sand filters at the rate of from seventy-five to one hundred and fifty million gallons per acre per day, then flowing to a reservoir for distribution by pumping.

The slow sand process is particularly adapted to purifying water without color and with comparatively little suspended matter. The mechanical process will successfully handle any type of water, regardless of color of turbidity, and operates at maximum efficiency when raw water conditions are worst.

Ordinarily, the first cost of a mechanical filter installation is considerably less than that of slow sand, and occupies but a fraction of the area required by the latter, while the operating costs are considerably higher than the slow sand method, due largely to the necessity for using coagulant.

For the purpose of acquiring information to enable us to advise the administration, we visited mechanical filter plants at Montreal, Que.; Little Falls, N.J.; Cincinnati, O.; Toledo, O.; Columbus, O., and Niagara Falls, N.Y. We also viewed the slow sand plants at Philadelphia, Pa.; Pittsburg, Pa., and Washington, D.C.

At each of these cities the type of plant used was giving satisfactory results.

At Philadelphia, we found that pre-filtration was necessary before admitting the water to the slow sand beds. This pre-filtration was accomplished by what is known as a "roughing filter," which is in effect a mechanical filter without the use of coagulant, and which removes from the water the greater portion of the suspended matter, thereby enabling the slow sand beds to be used at a rating much above normal.

At Pittsburg, they were having considerable trouble with the water, and were making plant additions to overcome same. This, however, was not due to any demerit of the slow sand method, but is accounted for by the chemical quality of the raw water.

At Washington, the water travels many miles from the source before it reaches the filters, sedimentation taking place in the channels and in certain basins en route.

The mechanical filters above referred to were also giving excellent satisfaction. Especially good results were obtained at Cincinnati, which may, in a measure, be accounted for by the fact that the water is allowed to settle for several days in reservoirs, prior to entering the plant.

The works at Montreal are the most recent in point of construction.

The Medical Officer of Health and Alderman Rowland, chairman of the local Board of Health, also visited a mechanical plant at New Orleans, La., which is giving excellent results.

The plants of both types visited were handling river waters.

The slow sand plant located on Toronto Island, consists of twelve beds, having an area of .8 acres each, designed to handle a maximum of five million gallons per acre per day, or four million gallons per filter, making a

maximum of forty-eight million gallons per day. However, it is necessary to have at all times at least two filters out of operation for cleaning purposes, making the average output of the plant forty million gallons per day. As a matter of fact, we have, for a considerable time, been operating at the rate of forty-three to forty-eight million gallons per day—considerably in excess of its designed rating.

To make provision for a maximum daily capacity of one hundred million gallons, Mr. Allen Hazen, the expert retained by the city, advises an addition of thirteen slow sand beds, each having an area of .8 acres, which would guarantee an average daily output of sixty-seven million gallons, after making allowance for the beds inoperative because of cleaning operations. For short periods this output could be increased to ninety million gallons per day.

This addition, together with the necessary pumping plant and appurtenances, would cost approximately one million dollars. The cost of operation per million gallons, excluding pumping and capital charges, is estimated by Mr. Hazen at $1.83. This seems to be a fair figure.

A mechanical filtration plant, capable of delivering a maximum of sixty million gallons per day, would cost approximately one million dollars—equal in amount to the slow sand addition.

While we have hereinbefore stated that the first cost of a mechanical filtration plant is considerably less than that of a slow sand, it does not hold good under local conditions, where very expensive foundation work must be provided owing to the sand formation of the Island.

The first cost of each type of plant being practically identical, the annual charges on capital account are not included in the comparisons following.

In mechanical filtration, an additional head is required to operate the filters, over and above that requisite in the slow sand method. Making provision for this additional lift, Mr. Hazen estimates the cost of operation per million gallons, exclusive of capital charges, to be $4.80, which, having regard for our investigation, appears a reasonable figure.

For the purpose of illustration, assuming the average daily pumpage for the year 1914 to be fifty-five million gallons, handled exclusively by slow sand filters, the approximate cost, excluding pumping and permanent charges, would be $36,737. If thirty-two million gallons were filtered through the present slow sand beds (their average normal rating), and twenty-three millions through mechanical filters, the annual cost would approximate $61,670, showing a difference of $24,933 in favor of slow sand. In later years, if the proportion of the total supply through mechanical filters largely increased, as it naturally would, the cost difference in favor of slow sand would be greater.

From the foregoing, you will observe that, from point of operating cost, the slow sand process is very much cheaper than the mechanical.

We have found in the operation of the Island plant that, at times of easterly storm, the suspended matter carried from Scarboro', and particularly the fine sand carried in the water, has rendered the filters almost inoperative. Our experience in 1912 showed this condition to obtain for four periods, and while by dint of great effort, we have never come to the point where actual cessation of filtering operations was necessary, we feel that a long continued easterly storm would probably so clog the filters as to render the use of raw water necessary.

Again, from the inset of frost in the fall until the advent of warm weather in the spring, it is not possible to wash the sand scraped from the filter beds, by the methods provided, inasmuch as the pipe lines, etc., would freeze and burst, and the sand and water would be frozen during the washing process. To overcome this, it was found necessary last summer to build a storage sand bin in each filter, wherein the sand scrapings for the winter were held. We have been working night and day since spring to wash this accumulation, plus the sand from the beds in operation, and the quantity necessary for re-sanding.

The complete construction of a slow sand filtration plant would take approximately three years, while a mechanical unit should be installed and in operation within eighteen months.

We deem it unfortunate that the filtration plant should have been erected at Toronto Island. The ideal place for such installation would have been on Garrison Common, which is within a convenient distance of the main pumping station, and would have been the strategic point at which, if necessary, other than lake water could have been filtered.

However, the fact that upwards of $800,000 has been invested in the Island plant compels the retention of the Island as a filtration site, unless the present plant be abandoned, which we, of course, cannot advise.

The formation of the Island is such as to render it an undesirable location for permanent construction of this nature, and the very extensive dredging operations which the Harbor Commissioners purpose undertaking, may cause such changes as to imperil the present or any future installation which may be built thereat. This possibility may be remote, but is of sufficient moment to justify us directing your attention thereto.

The continuity of a filtered water supply for 365 days per year, is in our opinion the dominant factor in the consideration of this proposition. A shut-down during a storm period would entail the use of raw water by the citizens, at a time when it is usually most dangerous, least amenable to chlorine treatment, and liable to produce epidemic.

While the slow sand method shows, on a pumpage basis of fifty-five million gallons per day, a saving of $24,933 per year over the mechanical system, we, your officials charged with the duty of providing an absolutely continuous and safe supply of water, are, irrespective of cost considerations, forced to recommend the adoption of the mechanical system of filtration.

The report was signed by R. C. Harris, Commissioner of Works; Geo. G. Nasmith, Director of Laboratories, Department of Health, and Chas. J. Hastings, Medical Officer of Health, and was adopted by the Works Committee.

The International Congress of Mining, Metallurgy, Applied Mechanics and Practical Geology is to be held in London in 1915. Several preliminary meetings of the Organization Committee have already been held, and a decision arrived at that the sections of the Congress be divided into four groups as follows:—Group 1, mining; section A, coal mining; section B, metal mining; Group 2, metallurgy; section C, ferrous metals; section D, non-ferrous metals; Group 3, applied mechanics; section E, mechanical engineering; section F, chemical engineering; section G, electrical engineering; Group 4, geology.

THE INCREASING COMPLEXITY OF MUNICIPAL GOVERNMENT

INTERESTING HISTORICAL REFERENCE TO TORONTO'S DEVELOPMENT IN MUNICIPAL GOVERNMENT — A REVIEW OF THE EVER-WIDENING RESPONSIBILITIES WITH WHICH CIVIC AUTHORITIES DEAL.

By His Worship the Mayor of Toronto, H. C. HOCKEN, Esq.

THE subject which I have chosen for a brief paper is "The Increasing Complexity of Municipal Government."* It will be admitted, I think, by all who have anything to do, at the present day, with the government of our large cities that the contrast between the present and former days is a very striking one with respect to the range and importance of the matters which are dealt with in our municipal administration. In earlier days the administration was simple; in the present day it is complex, and is increasing in its complexity.

The Toronto *Globe*, in its issue of June 11th, 1913, contained the following paragraph:—

> "When the late Dr. Goldwin Smith, a keen critic of public affairs, was asked why he did not take an active part as a municipal representative, he said he had to confess his lack of ability. He went on to point out that while honesty and common sense were sufficient in a small municipality, the great city's management called for special knowledge in a multitude of problems in such matters as finance, engineering, sanitation, hydraulics, transportation, and traffic management."

In these words the difference which exists at the present time between the government of a small municipality and that of a large one is very succinctly stated; and also, I think, the difference between the government of a large city in earlier days and that of the present day.

By way of illustration, let us consider the City of Toronto, which I have the honor to represent. The earliest printed financial statement of Toronto which I am able to find is that for the year 1858. The ordinary expenditure for that year may be set down under the following principal headings:—

Public hall, public markets, weigh houses; street watering, lighting, and repairing; fire protection, by a volunteer brigade; education—common schools and grammar school; police protection, and administration of justice; health protection—in a small way, including, it may be remarked, care of "cholera shed"; care of insane; public walks and gardens; care of poor, principally by the House of Industry; construction of sewers.

The financial statement for 1880 does not differ much in its scope from that of 1858. The principal changes are the substitution of a permanent fire brigade for that of a volunteer force, a larger proportionate expenditure for street watering and repairing, and in the interval the transfer of the care of insane persons to the provincial government. Parks in 1880 were given more attention, street cleaning formed a more important item, and there was some expenditure for a smallpox hospital and for vaccinations.

An examination of the estimated expenditure for the year 1913 reveals a vast difference in character and scope as well as in the magnitude of the figures. Under the headings "Works" and "Health" the change is a striking one. In former days the expenditure for protection of health was insignificant; to-day it is large. The Health Department, with a skilled and leading member of the medical profession at its head, is one with a large staff, combatting diseases of a contagious and infectious character, maintaining an isolation hospital and a smallpox hospital, and vaccinating people free. It tests milk and regulates its sale to see that the business is carried on under clean conditions. It sends its inspectors out to the country to examine the dairy farms and enforces compliance with sanitary regulations. It fights the white plague by sending out nurses to the houses of the poor to direct the care of those suffering from tuberculosis and to prevent others from being infected. It has a dental clinic which does a large work principally in treating the teeth of school children. It has a laboratory for contagious diseases, for testing milk, and for making a daily and continuous analysis of our city water. Plumbing construction and appliances are regulated and inspected, and house drains are supervised and regulated. In addition, a vast system of inspection is carried on to suppress insanitary conditions in houses and premises, and to prevent the growth of slum conditions. Food offered for public sale is also inspected, and the conditions surrounding its display, its handling, and its delivery are regulated. Perhaps in no department of civic government is the change so marked as in that of the care of the public health. It would be nearer the truth to say that this branch of our municipal government is altogether new. It has arisen out of the great advance made of late years in sanitary science and preventive medicine, and I think that in its detection of contagious diseases, in its limitation of them, and in its prevention of epidemics with attendant enormous loss of life and trade, the board of health is a paying insurance.

The people demand free libraries, and one was established in Toronto in 1883. The maintenance of our public library board takes one-quarter of a mill in the dollar of our annual taxation. Not only is there a large central library, but the residents of the outlying sections demand branches which are provided and maintained. Skilled and trained officials are in charge.

Children's aid societies, industrial schools for boys and girls, and a juvenile court for the discriminating and sympathetic treatment of boys and girls who commit offences which bring them into the hands of the police are among the new institutions of recent years with which we have to deal. The system of dealing with juvenile de-

*Read at the 13th Annual Convention, Union of Canadian Municipalities, July 15, 16 and 17, 1913.

linquents is largely preventive, and on the whole it is successful.

An industrial farm has been provided to which to send prisoners from the city jail, in order that regular and healthful work may restore them to physical vigor and enable them to overcome their craving for drink. Incidentally, they earn the cost of their maintenance.

A few years ago we established a public bath house. This has been so successful in a central location that baths have been demanded for other sections of the city.

The people call for band concerts in the public parks in the summer as well as free bathing facilities at the Island, and in the winter they call for skating rinks and toboggan slides in the parks.

We are establishing a public abattoir at a large expenditure for building and equipment.

In connection with street cleaning, the great area to be cleaned and swept, and the extensive system of garbage collection require the erection and equipment of incinerator plants at different points in the city, and a reduction plant outside the limits of the city where garbage is to be reduced and by-products utilized. The initial expenditure for all these plants will total about one million dollars.

Education is widening out. To the former common and high schools are added those for technical instruction, with a very large expenditure for building and equipment.

Public ownership of public utilities is the new order of the day. It began with the acquisition of the waterworks. It has extended to the establishment of a municipal electric lighting and power plant in close affiliation with the hydro-electric system of the province of Ontario, and the construction of street car lines by the municipality, and my hope is that before long we shall have ownership and control of street railway transportation and electric power distribution on every street and in every part of our city.

Main drainage, sewage disposal, storm overflow sewers, bridges and viaducts, waterworks problems and extensions, are all subjects which require careful thought and the employment of skilled engineers and experts. These are important matters with which the municipal rulers of earlier days were not required to deal.

All this increasing complexity of municipal government demands the service in the Council of men who have had some special training in municipal administration. It must be apparent to any thinking person that a man cannot approach this work, and render substantial service until he has had a chance of making a study of at least some of the problems with which a large city government has to deal in these days.

This ever-widening range of responsibility will compel the men who are elected to administer the affairs of the great cities, to specialize in the different departments of civic government. It is only by special application to particular problems on the part of a group of men sharing this responsibility that the best results can be attained.

When Toronto was a city of under 100,000 people, thirty-five years ago, one man was city commissioner and health officer. He inspected works in course of construction, and had charge of health, street cleaning, street watering, public markets, public halls, and other miscellaneous work. No city in Canada of a population of 100,000 would dream to-day of putting such a load on any official, because the duties of each branch have been so amplified that it would be a physical and mental impossibility for the official to carry the responsibility.

The people demand that our municipal government shall protect them and their property against criminals and fire. They ask for protection against disease, whether it comes from diseased persons or from food or water. They ask to be cleansed by public baths, and to be amused in summer and winter. They ask also to be provided with books and periodicals to read. In short, they ask to be guarded at almost every point, and as in the last analysis, they rule as well as provide the funds, their demands must be complied with. The experience of Toronto is, I believe, similar to that of other cities.

NEW HIGHWAY BRIDGE AT LYTTON, B.C.

The accompanying illustrations refer to a proposed structure to cross the Thompson River, just above its junction with the Fraser, at a site between the present bridge which is also shown, and the crossing of the Canadian Northern Railway. The new bridge will carry the main highway from Hope and Lytton in the direction of Lillooet and other northerly points.

The sub-structure is of concrete, and steel is being used in the superstructure, the whole resting on a good rock foundation.

Fig. 1.—Bridge at Lytton, B.C., Which is Being Replaced.

There will be 209 feet of timber trestle approach with a similar length of grading on the southeastern bank of the river. Over the bridge the roadway will be 16 feet in width, and will be constructed of 4-in. plank protected on either side by a 4-foot hand railing with posts 7 feet 7⅛ inches apart. The roadway plank will be supported on 6-inch joists of varying depth, according to camber, on steel I-beam stringers. A crowning one inch thick will be applied to the top of the floor.

The bridge itself will consist of a 250-foot truss span, 35 feet deep, together with two 70-foot plate girder spans, one on either side and an additional 50-foot plate girder span carried on steel bents and concrete abutments. The large truss span will rest upon concrete piers seventy feet above low-water, while the distance of the resting surface of the truss above the extreme high-water level will be 7½ feet.

The bridge is designed to carry a live load of seventy-five pounds per square foot on the 250-foot truss, and one hundred pounds per square foot on the shorter spans, together with a concentrated load of a 16-ton road roller.

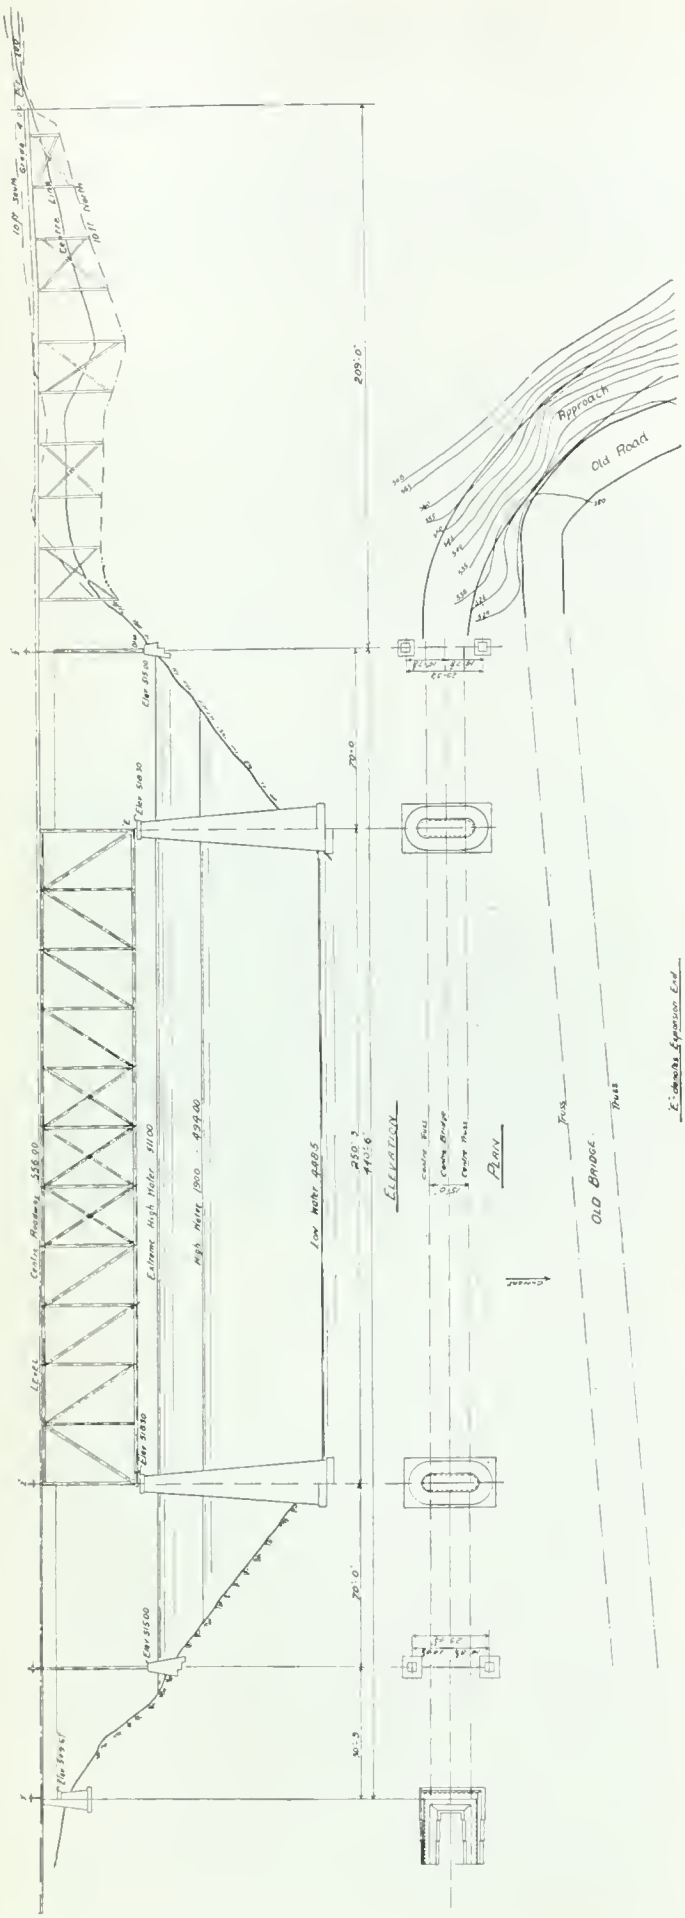

Fig. 2.—General Plan of Proposed Bridge Over the Thompson River at Lytton, B.C.

The level of the new bridge will be forty feet higher than that of the present structure, which is illustrated in Fig. 1. The 215 tons of steel will be fabricated by the Canadian Bridge Company, while the 2,000 yards of concrete, erection of steel, and the other work at the site will be carried out by the Graff Construction Company. The bridge is being built by the Provincial Department of Public Works, J. E. Griffith, chief engineer, and was designed by E. A. S. Stone, M. Can. Soc. C.E., M. Inst. C.E., consulting engineer, Vancouver.

Fig. 3.—Sections at Abutment and Trestle, Lytton, B.C.

COPPER CLAD WIRE LITIGATION DISMISSED.

Important litigation in regard to copper clad wire which has been contending in the United States Court in Pittsburgh, Pa., for the past two and a half years between Duplex Metals Company of New York, complainant, and the Standard Underground Cable Company, Pittsburgh, Pa., defendant, was virtually decided June 25th, when the case came before the Court on motion made by complainant to dismiss the bill in respect to patent infringement. The bill as originally filed charged infringement of the patent and infringement of a trade mark. The motion made by complainant was to dismiss without prejudice; that is to say a dismissal leaving the complainant in a position to renew the suit at its pleasure. The motion was opposed, defendant contesting that the bill should be dismissed in this regard and a dismissal should be on the merits of the question. The Court so ordered, the order reading:—

"Complainant having admitted that defendant's product referred to in the proofs herein does not infringe the Monnot Patent in suit No. 893932, it is ordered and adjudged and decreed that the bill of complaint herein, in so far as it is based on alleged infringement of said patent be, and the same hereby is dismissed on the ground that defendants have not infringed said patent."

The Order of the Court directs that the complainant pay the costs. The only portion of the suit not thus disposed of is in regard to the right to use the trade name "Copper Clad" and which is expected to go to a hearing in the early fall.

ROAD RESOLUTIONS ADOPTED BY THE 1913 CONGRESS

CONCLUSIONS ARRIVED AT BY THE VARIOUS SUB-SECTIONS—THE NINE ROAD QUESTIONS AND FINDINGS RELATING TO EACH—A SUMMARY OF THE WORK OF THE THIRD INTERNATIONAL ROAD CONGRESS.

THE resolutions adopted as a result of the careful study relating to the nine questions before the International Road Congress are given below. The Congress included two sections, each of which were further divided into two sub-sections. The first section's investigation pertained to construction and maintenance. Sub-section A dealt with the roads outside of larger towns and cities, while Sub-section B had before it the consideration of roads in cities and large towns. The second section, on traffic and administration, consisted of Sub-section C, dealing with traffic and vehicles, and Sub-section D, on administration, finance and statistics. The discussions of each section were distinct from those of any other, and each had its own executive committee. In a number of instances, however, two sub-sections sat together.

First Question.—Planning of Streets and Roads.—This was dealt with by Sub-sections A and B combined. When the discussions were summarized the following resolutions were adopted:—

1. As a general principle, it is better that new main roads be constructed to pass outside rather than through towns, and that, where an existing main road passing through a town is unsatisfactory for through traffic, it is often better in preference to widening an existing narrow main road through the centre of a town, new roads should be planned according to the principles of the science of town planning.

2. Gradients on new roads should be as easy as possible, having regard to the physical character of the country through which they pass, and they should be easier where there are curves, trams, or a preponderance of heavy traffic.

3. The radii of curves in roads used by fast traffic should, where practicable, provide the best possible and an unobstructed view, and that where this is not possible, the curve being of too short a radius, means should be provided whereby the approach thereto is in some way clearly indicated.

4. Except where it is possible to provide special reserved spaces, tram tracks are best placed in the centre of the roads, and that where so placed it is desirable to provide space on either side for two tracks for vehicles.

5. The main traffic roads should be so designed that spaces are provided for tram tracks, fast and slow traffic, and standing vehicles; and in such a way that they can proceed without unduly intermixing. In fixing building lines along what may ultimately become main roads, regard should be paid to ultimate requirements. Adequate space should be provided between the buildings, and powers for enforcing this should be held by all authorities who decide the widths of roads.

6. That the planning of main road communication outside towns should be at once undertaken; it is a matter of national importance in regard to which some initiative should rest with a Central State Authority, and the action of Local Authorities should to some extent be regulated or supervised by Central State Authorities.

Second Question.—Types of Surfacing to be Adopted on Bridges, Viaducts, etc.—Sub-sections A and B sat conjointly concerning this question also, and the following are the resolutions which were passed:—

1. The choice of road surfacing for bridges depends on the nature and intensity of the traffic, the local conditions, such as permissible first cost, kinds of material readily available, and climate. For light bridges the choice is largely influenced by the weight of the surfacing. Public safety and convenience should be first regarded rather than questions of comparative cost.

2. On short bridges in town or country, it is desirable than the surfacing should be the same as that on the adjoining streets or roads.

3. In forming the roadway on bridges, special care should be taken to secure proper drainage, and to prevent the harmful percolation of water. With longitudinal gradients of at least 1 in 50, the cross section of the surface may be made nearly flat and the dead load thus reduced.

4. As a general rule, the surfacing of a bridge should be waterproof, capable of resistance to wear, durable, and of a weight appropriate to the structure of the bridge; it should also be as smooth as possible without being slippery.

5. Plank surfacing on bridges is light, and its first cost is low. Its cost of maintenance is, however, excessive, except where the traffic is light. Its extreme liability to damage by fire is a serious disadvantage. It should not be adopted, except in remote districts in which there is an abundance of cheap timber, and where a more desirable form of surfacing is not easily obtainable. Single plank floors are only suitable for very light traffic. For moderate or heavy traffic, two layers of planking, the lower of which is creosoted or otherwise protected from rapid decay, should be used.

6. Macadam, or ordinary broken stone surfacing, on timber planking, is not always satisfactory on account of its great weight and its permeability. Macadam is, however, quite satisfactory for massive bridges in rural districts, if the substructure has a proper damp course.

7. Macadam, bound with tar, or other waterproof and elastic material, is useful and economical for the surfacing of rural bridges with moderate traffic, when the spans are short or the structure is massive.

8. Wood paving block, 3 to 5 inches thick, is an ideal surfacing for bridges in most cases. It is light and durable and can be laid on concrete, or, when weight must be minimized, on a timber subfloor, which should be creosoted. Special care should be taken in the selection, treatment and laying of wood blocks for bridge paving, to avoid troubles due to expansion and contraction of the blocks or of the metal structure.

9. Asphalt, in various forms, is an excellent surfacing material for bridges with easy gradients,

on which the traffic is not confined to definite lines or very heavy.

10. Stone paving, carried out either with ordinary hand-dressed setts or with small setts (Durax; Kleinpflaster), laid on concrete and bound with cement or pitch, makes excellent and economical surfacings for bridges with heavy traffic. However, it is only suitable in cases where questions of the weight of the surfacing or of noise are of no importance. The thickness of the layer of sand interposed between the setts and the foundation will be decided in the same way as with an ordinary carriage-way, in town or country, as the case may be.

11. For movable bridges, and for non-rigid suspension bridges, the surfacing should be light and easy to attach to the bridge platform. The trials made in France and Belgium with old mine cables, or other fibrous substances of even less cost, and with such materials impregnated with tarry, bituminous or asphaltic materials should be encouraged.

Third Question. — Construction of Macadamized Roads Bound with Tarry, Bituminous or Asphaltic Materials.—Sub-section A dealt with this question and arrived at these resolutions:—

General Conclusions.—By the use of bituminous, including tarry or asphaltic binders, we may obtain a number of different forms of road crust, which may be employed with advantage, according to the various conditions of the road as regards traffic, locality, and climate.

The exact value and duration of life of these various road crusts, taking into account traffic, climatic conditions, and the methods of construction, remain to be determined.

For this purpose it is advisable to draw up a uniform system of tests, measurements and records, under the following headings:—

1. Physical and local conditions. (Plans, cross-section, slopes, camber foundations, subsoil.)
2. Materials employed, petrological analysis, dimensions, composition of the binding agent.
2a. Method of construction, date of construction.
3. Census of traffic on the section under review.
4. Climatic conditions affecting the road.
5. Periodical measurement of wear.
6. Periodical examination of the state of the road crust.
7. Actual cost of the road crust: (a) As regards cost of construction. (b) As regards maintenance cost.

The standard form in which the information is to be furnished will be drawn up by the Permanent Commission.

Particular Conclusions. — I. Foundation and drainage.

Confirming the conclusions adopted in 1910 by the second Congress (Brussels, 2 Question), which called attention to the advantages of a dry foundation and a sound subsoil, the Congress especially insists upon the great importance of efficient foundations in the case of road crusts bound with bituminous (including tarry or asphaltic binders) for the following reasons:—

(1) The road crust being expensive, it is important to give it a base which will increase its life.

(2) As the weight, speed and intensity of the traffic continually tend to increase on roads considered worthy of such a crust, it is best to provide a foundation which has been so constructed as to secure for the crust the best possible conditions of resistance to wear.

II. Dimensions and shape of metalling.

(1) When an ordinary macadamized road crust is constructed with a view to being tar-sprayed, it should be constructed of hard metal, with sharp edges, and broken as nearly as possible to a cube of the dimensions of from 4 to 6 c/m.

(2) In the case of bituminous including tarry or asphaltic macadam, carried out by the mixing process, the dimensions of the metal may be so selected and graded as to form a compact road crust with the fewest possible voids. The dimensions of the largest metal may vary according to the nature of the stone and of the traffic. When the process of construction employed requires more than one layer of material, the upper layer or wearing crust may be formed of smaller metal.

(3) In respect of bituminous including tarry or asphaltic road crusts constructed by the penetration process, the trials and tests now being carried out in various countries should be continued, taking care only to employ metal of as cubical a shape as possible, and with sharp edges, at any rate, for the portion of the road crust nearest the surface.

(4) It is understood that further experiments will also be carried out in the use of the other methods, and especially 1 and 2.

III. Employment of partially used metal.

By carefully eliminating all particles of mud and organic matter, it is possible to successfully make use of partially worn materials, on condition that they are not employed for the surface of the road crust.

IV. Relative importance of patching.

It is agreed that it is absolutely necessary to carry out repairs, in the case of all bituminous including tarry and asphaltic road crusts, immediately the necessity for them arises.

V. Permissible wear.

The complete renewal rendered necessary by wear must be carried out immediately the depth of the road crust is below a given limit of safety, or when its waterproofing qualities have become so poor that the road will unduly suffer from climatic conditions.

VI. Various means of employing tarry, bituminous and asphaltic materials.

In using these materials, both in the penetration method and the mixing method:—

(a) It is preferable to use dry stone in order that it may adhere well to the binder. In the mixing method the stone must always be dry, and if necessary it must be heated.

(b) One must never lay a top crust upon a soft or damp foundation. One should preferably carry out the work in fine weather.

(c) One must never employ too much binder, but only a sufficient quantity to bind the portion of the road which is being rolled.

(d) One must never employ road rollers which are too heavy.

VII. Tests and chemical analysis.

The advantages of analyses and methodical laboratory tests, and their necessity in the case of bituminous binders, are unanimously recognized.

It would be of advantage to obtain uniformity—

(1) As regards the specification of the principal characteristics of these binders.

(2) As regards the methods of testing for drawing up these specifications. The Permanent International Commission will be entrusted with the work of enquiring into the best way of standardizing the above.

VIII. Climatic effects.

It appears to be generally agreed that certain tarry, bituminous or asphaltic road crusts (as is also usually the case with all smooth and waterproof road surfaces) may become slippery under certain conditions of weather.

This may be remedied by strewing the surface with coarse, sharp sand; and in most cases a good cleansing of the surface will usually prevent the carriage-way becoming slippery.

IX. Effects on public health, etc.

Sufficient information is now available to enable engineers to select and specify bituminous binders which will have no prejudicial effect upon public health, fish life, or vegetation; but which, on the contrary, will conduce to conditions of considerable hygienic advantage.

X. Cleansing and watering.

It is recognized that carriage-ways properly treated with bituminous including tarry or asphaltic materials require less sweeping and watering than ordinary water-bound macadamized roads, and that they allow of considerable economy being effected under this head.

Fourth Question.—Wood Paving.—The resolutions which were adopted by Sub-section B are the following:—

1. Where gradients permit, wood block pavement is very suitable for streets where the traffic is great, but is not of the exceptionally heavy character usually existing on streets near docks or similar centres of industrial traffic. It should be used where a noiseless pavement is desirable.

It is of great importance that a concrete foundation should be laid of sufficient strength to carry the traffic passing over the pavement.

2. Great care is necessary in the selection of the proper timber for the purpose, and all soft wood blocks should be thoroughly impregnated with a well-proved preservative before being laid.

3. In view of the varying results given by wood pavements, according to local circumstances, it is desirable that further investigations and laboratory experiments should be carried out in connection with the selection of the timber and of the impregnating preservative.

4. Every precaution should be taken in laying the blocks to prevent, so far as possible, the entry of water through the joints.

4a. Hard woods give varying results according to local circumstances, and it does not appear desirable to recommend them for roads with intense traffic in large cities, unless some means are devised to effectively prevent the rapid destruction of the joints and the resulting destructive effect on the concrete below. If these woods are employed, it is desirable not only to prevent the percolation of water through the joints to the foundation, but also to consolidate the blocks as far as possible, so that they may not become rounded at the edges.

Soft woods obtained from suitable kinds of trees, and especially from resinous species, are equally suitable for roads with a comparatively heavy and intense traffic as well as for roads with a light and infrequent traffic. In the latter, however, the blocks are liable to rot if they have not been suitably pickled. It is also desirable to make the joints as small and watertight as possible. On the other hand, their comparatively rapid wear on roads with great traffic should encourage one to make exhaustive investigations into the best means of treating them, so as to increase their strength without prejudice to their elasticity.

5. Subject to certain precautions, such as impregnating of the wood, waterproofing of the joints and surface, frequent cleaning of the roadway, etc., there is no objection to wood pavement from the sanitary point of view.

6. The spreading of gritting is necessary under certain conditions and in certain weather (especially on hard wood paving) to prevent the surface becoming slippery, but the gritting should be done with suitable small gravel chippings or sharp sand, so as to avoid, as far as possible, any injury to rubber tyres.

Fifth Question.—Methods of Lighting Public Highways and Vehicles.—This was considered by Sub-sections C and D combined, and the following resolutions unanimously adopted:—

The section adopts the following resolution unanimously:—

I. For the purposes of a general determination of methods of lighting, highways may conveniently be divided into three classes as follows:—

(1) Important streets in cities, towns or other urban areas in which the traffic after dark is considerable in volume.

(2) Important suburban roads in the vicinity of large towns.

(3) Rural roads in open country, and having regard to modern conditions of traffic, it is essential that adequate lighting by means of fixed lights should be provided in classes 1 and 2.

II. As a general principle in the lighting of all highways which require to be lighted by means of fixed lights, the method of lighting to be adopted should be such as will provide an illumination as uniform and free from glare as possible. The amount of illumination and the position of lamps must be determined with reference to local circumstances.

III. It would be impracticable to light rural roads in open country generally by similar methods to those adopted in urban streets or suburban roads, and the lighting of vehicles running or standing on rural roads at night is, therefore, of the highest importance.

IV. Every vehicle, whether standing or moving, should carry a light of sufficient power at night which can, except when specially authorized, be seen from the rear as well as from the front of the vehicle.

(2) Every motor car must carry after nightfall, two lighted lamps in front, and one at the back; if it is able to move at a high speed it must be fitted in front with a headlight of sufficient illuminating power to light up the road or path for at least 50 yards to the front. In inhabited places where the ordinary lighting is sufficient to allow motorists to see their way and to be easily seen, the light of the

headlights must be limited to that of the ordinary lamp.

V. It is desirable that all obstacles across a road, such as gates, and particularly gates at railway level crossings, should be painted white and in other colors in alternate parts, and illuminated by fixed lights which are lighted at dusk.

(2) It is desirable to paint white paint or indicate by some other method all danger signal posts, direction posts and other posts, milestones, wheel kerbs, bridge abutments, etc., or other special features, the indication of which would aid travellers, or conduce to the safety and convenience of the traffic.

VI. One and the same color should be universally adopted as the color for danger signals.

The meeting also adopted the following resolution:—

1. It is desirable that each Government should do away as soon as possible with colored lights on automobiles.

2. The Congress expresses the wish that regulations should be made to compel drivers of herds of cattle to make their presence known.

Sixth Question.—Observations noted since 1908 as to the Various Causes of Wear and of Deterioration of Roadways.—Sub-section C adopted these resolutions:—

1. Weather conditions are amongst the most powerful influences which cause deterioration of roads, and that the destructive effect of weather can be minimized by effective waterproofing of the road surface, with suitable drainage for the foundation.

2. Any considerable volume of traffic, consisting of either heavy motor vehicles or high-speed light motor cars has a seriously damaging effect on water-bound macadam roads. The damage caused is effected by the balancing of the motor; the ratio between propelling power and adhesive weight; the weight of unsprung portions of the motor; the progressivity of action of the brakes; the system of springing; the type of tyres employed, the diameter of the wheels, the width of the rims, variation of speed and adherence, and other factors.

3. The damaging effect of heavy motor vehicles can be minimized by the use of wheels of large diameter; tyres of a width properly adapted to the weight of the axle load; rubber or elastic tyres and suitable springs, and that all reasonable means of reducing the damage to roads caused by such vehicles should be enforced.

4. Light motor car traffic does not cause serious or exceptional wear or damage in the case of properly made macadam roads which have been properly treated or bound with tarry, bituminous or asphaltic materials, except in sharp curves.

As regards horse-drawn vehicles, it is desirable also to study the relations between load, width of rims and diameter of wheels, and more especially the system of shoeing horses. It is also necessary that power should be given to Local Authorities to prevent the deposit of refuse from the fields and earth upon the roadway by the wheels of agricultural carts.

5. There is still a great lack of precise information in regard to the various causes of wear and deterioration of roadways, and that it is desirable to collect more information compiled on carefully devised scientific methods, standardized as far as possible for the purposes of comparison, and to make further systematic study of these causes.

Seventh Question.—Regulations for Fast and Slow Traffic on Roads—Sub-section C investigated existing regulations, and adopted resolutions as follows:—

1. That all regulations for the control of road traffic should be based on the principle of allowing the speed practicable for each different kind of vehicle consistent with public safety, general convenience, and the normal wear of the road.

2. That regulations for the conduct of fast and slow traffic should be as few and simple as possible, and should be such as can and ought to be universally adhered to and enforced.

3. That in all large cities there should be a Traffic Authority, on whom should be charged the duty of studying and dealing with street traffic problems, the powers of such authority and the co-ordination of such powers with those of other public authorities being matters of detail which must be settled by public authorities on consideration of the circumstances and conditions of each large city.

4. That there should be ample provision of traffic controllers (such as the police in London) with adequate powers to regulate the traffic, not only at congested points, but throughout the course of crowded streets.

5. That having regard to the increased danger which is necessarily created by the conditions of modern traffic it is important that drivers should be carefully and systematically trained, and that children should be specially taught how to provide against the dangers of the road.

6. That except where local circumstances render it absolutely necessary, no obstructions, such as lamp-posts, tramway standards, etc., should be placed in the centre of a road, except necessary refuges for pedestrians crossing.

7. No obstruction of the public highway should be permitted either by vehicles standing unreasonably, or travelling at an obstructing speed, or by things placed on the highway. Exception must, however, be made for depôts required for the work of maintenance or repair of the road, or for work being carried out by duly authorized and competent authorities, but in every case all necessary steps must be taken to ensure the safety of traffic.

The meeting unanimously adopted the following resolution:—

8. Regulations for roads and traffic must aim at defining the rights, duties, and responsibilities for each kind of traffic, in order to avoid the causes of accidents and damage and to ensure the maximum of order and liberty.

Eighth Question.—Authorities in Charge of the Construction and Maintenance of Roads. Functions of Central Authorities and Local Authorities.—Sub-section D passed resolutions concerning this question, which are as follows:—

The system of road administration in any country must be in harmony with the general system of government prevailing in that country, and the political genius of its people. It is impossible, therefore, to lay down any general rule of universal application as to the extent to which the road organization of any country should be centralized or decentralized.

In countries where maintenance of roads by local authorities has hitherto been the prevailing system, the modern engineering problems of road construction raised by the increased motor traffic are creating a demand for greater centralization in the belief that this will tend to greater expenditure on the roads, but in the opinion of this Congress it is not desirable that the maintenance of the roads should be vested in a central authority, but should be decentralized as far as is consistent with good administration, and that assistance should be given by the State contingent on the roads being maintained up to a prescribed standard.

In those countries where centralized systems of administration already exist, it is desirable that these systems shall be developed and perfected.

A principle that can be laid down as of universal application is, that the unit of highway administration shall be sufficiently large and command sufficient resources to employ and adequately remunerate a competent staff.

It is desirable that the engineering staff shall be organized on a national basis, and shall consist of:—

(a) Chief engineers, with powers of inspection, and report to the authority making grants.

(b) Divisional engineers in charge of administrative units.

(c) Assistant engineers, recruited by examination from engineering students who have received a practical training following upon a good general education, and an engineering education at some recognized engineering school or university. Promotion shall be by merit.

Ninth Question.—Finance of the Construction and Upkeep of Roads—Provision of Revenues.—Sub-section D decided as follows:—

1. The expenditure on the maintenance and improvement of:—

(a) The roads which serve as main routes of communication between important places in any country, or

(b) Roads which are used mainly by long distance traffic unless such expenditure is borne wholly out of the National Revenues under a system of State Administration of roads (which system is practicable and suitable in the case of some roads in some countries) should be mainly paid for out of National Revenues, whether or not such roads are locally administered and maintained, subject, where local administration prevails, to the supervision of a central government authority both as to efficiency and expenditure.

2. It is desirable to abolish, so far as possible, all tolls on public roads, but it is equitable that vehicles which, on account of their weight or weight combined with speed or any other exceptional circumstances connected with either the vehicle or use of the road, cause special damage to roads beyond the wear and tear of the ordinary traffic of any district, should be subject to special taxation, the proceeds of which should be earmarked for expenditure on roads.

3. Borrowing money for new road construction and for the periodic renewal of the surface coating of a road is consistent with sound financial principles, provided that the loan period in the case of loans for renewals, is kept well within the life of the surface coating.

HYDRO-ELECTRIC INSTALLATION, CITY OF TOKYO.

The unparalleled industrial boom Japan experienced during the last few years has brought with it an enormous increase in the demand for cheap electrical energy throughout the country and particularly in the city of Tokyo. In 1908 the Tokyo Electric Light Company completed their hydro-electric power station on the Katsura River about 100 miles from Tokyo, at this time the largest and most important power station in Japan. The total output of this plant was 27,500 H.P. developed by six Escher Wyss Francis turbines direct coupled to generators of Siemens make. One year later the company had sold the whole of the energy developed and a second plant of increased capacity had to be taken in hand. It was decided to develop a fall ten miles down stream on the same river, where 42,000 continuous horsepower could be obtained. The minimum flow of the river was measured to be 850 cubic feet per second, while the net head available varied from 368 feet to 396 feet maximum. By providing a reservoir of sufficient storage capacity the plant could deal with a peak load of 50,000 H.P.

With a total capacity of 75,000 H.P., not including the power required by the auxiliaries, this new installation is again the greatest power plant in Japan, comprising six main turbines of the same make, each of 12,500 H.P., including the oil pressure plant as well as the distributing piping with the necessary gate valves.

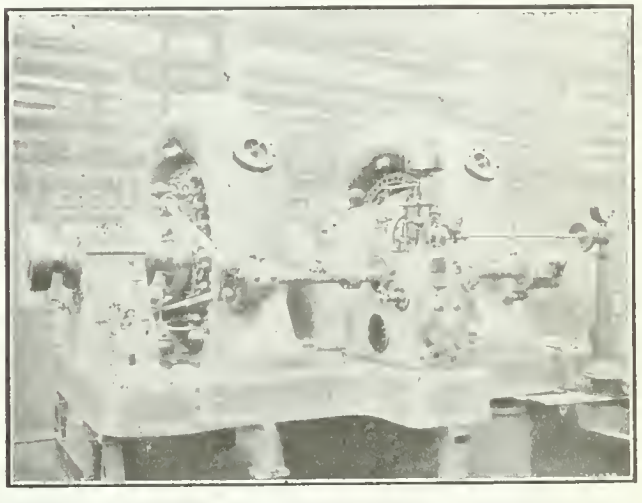

Fig. 1.—Turbines Used in Tokyo Hydro-Electric Plant on the Katsura River.

Regarding the layout of the plant it may be mentioned that the water is brought through a tunnel to the forebay and from there in six parallel pipelines of 700 feet length and 6 feet diameter to the turbines. Each turbine has its own pipeline, the exciter turbines being fed by a seventh pipe of smaller diameter.

The main turbines are arranged in two groups, each consisting of three units on both sides of the switchboard. The distributing pipes and valves are on the lower floor, thus leaving the engine room proper free and allowing for easy access and attendance. For the transformers and connections a second building is provided. The pipeline for each main turbine is connected by means of a conical pipe to a gate valve of 4 feet 7 inches diameter operated hydraulically by pressure water taken from the penstock. A cast steel Y piece and bend connect the turbines to the main gate valves.

The main turbines are shown in the illustration. They are Francis turbines of the twin spiral type with horizontal shaft running at 375 r.p.m., and are coupled direct to the alternators, the coupling flanges being forged on to the shaft. Each unit is mounted on a solid cast iron base plate grouted into the engine room floor. This arrangement ensures a very accurate and simple lining up on site, easy dismantling and remounting for repairs, and equal pressure on the foundations. The shaft runs in two ring lubricated bearings of ample dimensions mounted on pedestals. The bearing on the free end is fitted with thrust collars. The lower bushings of both bearings are hollow and water cooled. The runners are made in special bronze and screwed on to flanges forged on to the shaft. The spiral casings are made in cast iron reinforced by steel bolts and guide ribs cast in. The guide apparatus is arranged outside the turbine casing, thus making all links and bolts accessible. The guide rings and covers in contact with the water have cast steel linings, which are easily interchangeable in case of wear. To reduce the distance between the bearings the draft chest has an elliptical form on the bottom. An intermediate pipe connects this draft chest to the wrought iron draft tubes.

The turbines are regulated automatically by oil pressure governors of Escher Wyss and Co.'s patent, mounted on the same bedplate as the turbine. The governor is the largest size of Escher Wyss and Co.'s standard type, fitted with speed changing device from the switchboard, further with quick closing device in case of falling off of belt, thus preventing the running away of the set. The servo-motor can be operated by hand instead of automatically, by means of a hand wheel regulating the access of the oil pressure to the one or the other side of the cylinder. The necessary pressure oil for the governors is supplied by an oil pressure plant.

To prevent dangerous pressure shocks in the pipeline under sudden throwing off of load of the turbines a relief valve is provided for operated direct from the governing gearing of the turbine. The relief valve works in such a way that when the governor closes the guide vanes to a certain amount, the corresponding area is opened in the relief valve. To prevent losses in water the relief valve closes automatically after a certain time.

The exciter turbines of 460 H.P. are coupled by means of flexible couplings to the exciters running at 600 r.p.m. The turbines are impulse wheels with two nozzles, each regulated by an oil pressure governor mounted on top of the casing.

The oil pressure plant consists of three pump groups, each group of sufficient size to feed four generator turbines and governors. Each pump is driven by a small impulse wheel of about 25 H.P. running at 80-100 r.p.m. Regulation is done by hand by throttling the pressure in the needle nozzle. All parts exposed to water pressure were tested to a test pressure of 350 lbs. per square inch.

The installation is working since October, 1912 and has been a great success in every respect.

George S. Rice, chief mining engineer of the United States Bureau of Mines has dedicated to public use a patent just issued by the Government for a hoisting cage which is primarily for use in rescue work, but can be used for other purposes. In describing his invention, he states that it has for its object the provision of a novel cage which shall have peculiar advantages in regard to portability and ease of assembling and disassembling. He adds that although not limited to such use it is of especial utility in mine rescue work as an emergency cage.

COAST TO COAST.

New Westminster, B.C.—Under an arrangement which the Provincial Government and the C.P.R. are upon the eve of entering, it is now proposed to have the new government highway bridge across the Pitt River finished many months ahead of the time originally set for its completion. The Provincial Government authorities are at present conferring with the railway officials with a view of securing the steel superstructure of the present railway bridge across the Pitt and placing it upon the concrete substructure of the new Government bridge, which will be located several hundred yards above the railway bridge and about where the ferry landings now are.

Vancouver, B.C.—In order to facilitate the work of protecting the forests from fire, the Provincial Government is building a number of trails through the danger spots, to aid in concentrating the forest guards in emergency. Work is going on at present on a trail from Gordon Pasha Lake to Powell Lake; a trail from Campbell Lake to Salmon River Valley, and a trail from Bond Sound to Kingcom Inlet. Cabins are being built along the trails at intervals to form resthouses for the firewardens, and supplies are being packed in over the trails, in order to prepare for emergencies. Superintendent George D. McKay has ready a supplementary list of fire guards who will be set to work as soon as the weather gives any indication of proving conducive to forest fires.

Toronto, Ont.—Toronto is to have the proposed auxiliary service to the waterworks pumping station, filtration plants and sewage disposal plant, in order to insure the necessary supply in case of interruption in the electrical transmission lines to the city. Chairman Ellis, Mayor Hocken and General Manager Couzens of the Toronto Commission had a conference with Hon. Col. Hendrie, Mr. W. K. McNaught, M.P.P., and Chief Engineer Gaby, of the Hydro-Electric Commission, and after a full and careful discussion of the joint report of the Provincial and city commission engineers regarding the proposed auxiliary plant it was approved. The report, which is signed by Messrs. Gaby and Couzens, does not assume to be comprehensive in character, and suggests two plans, part of which reads as follows:—"The power required for the civic requirements as outlined is over 14,000 H.P., and there are two broad lines on which a permanent auxiliary electric service to operate the plant can be dealt with:—(a) By the installation of generating plant within the city, to be given by steam, gas or oil engines; (b) connection with the system of the allied electric companies. A comparison of these two methods shows, in our opinion, the following among other advantages, in favor of the former under present conditions:—Greater rapidity in picking up the load; less delay in transferring the load after resumption of supply; greater reliability; the whole Toronto system would remain under the direct control of the Toronto Commission, and, therefore, under the general Hydro scheme; lower capital cost; economy due to utilizing the steam plant for the reduction of peak loads; ability to use the plant in cases of emergency in accordance with the terms of the agreement between the Provincial Commission and the city of Toronto; greater possibility of expansion in accordance with the requirements of the system and service. We, therefore, beg to recommend the adoption of scheme (a) in general principle, when the details can be carefully worked out and a report submitted to the Toronto Commissioners with a view to considering the vari-

ous commercial features which concern the undertaking under their control."

Montreal, Que.—Nearly seven million bushels more grain have passed through the Lachine Canal thus far in 1913, than for a similar period of last year. The exact increase is 6,911,919 bushels, or more than the total receipts for the month of May, 1912. Wheat, corn, barley, flax and oats are included in the shipments, which comprise a record for the Lachine Canal. The carriage of wheat alone is almost doubled this year, its total of something over ten million bushel being balanced against five million for 1912. Mr. Ste. Marie, canal revenue officer, predicts even a greater increase for the remaining months of the season. "The Fort William and Port Arthur elevators are not nearly exhausted yet," he said recently, "and the chief reason why shipments have not been even heavier than they have, is because Montreal elevators have not been able to cope with the onrush of grain that has been pouring into them since navigation opened late in April. When we have secured sufficient elevator accommodation at this port, Montreal will get all, or practically all, of the Canadian shipments from the West. The St. Lawrence route, besides being the shortest, is the most expedient for lake shippers, and we may expect to get more records broken when we supply facilities for handling the grain once it gets here."

Vancouver, B.C.—"The Burrard Inlet is a splendid place in which to locate a floating drydock. I should prefer a floating to a graving dock, which was in fashion forty years ago, but which has since grown too small or become unadaptable because the shipping centre has moved away. But Vancouver really needs a floating dock," said Mr. James Fowler, of Seattle, Lloyd's agent for the Pacific coast, to the sub-committee on harbor affairs of the board of trade when discussing Vancouver's requirements in the matter of docks. Mr. Fowler recommended the erection of a floating dock, 12,000 to 15,000 tons weight, for Vancouver harbor. It should be 600 feet long, and there should be at least 90 feet between the towers. Such a dock would satisfy the needs of this port for many years. A structure at Seattle, built for the Seattle Construction Company, approximately of this size, cost about $650,000. But it was built in sections, a method of which Mr. Fowler disapproved. "For Vancouver especially, where there is just now no centre of shipping, a floating drydock, which can be moved up the harbor as wharves are built toward the east, is vastly to be preferred to a graving dock," said Mr. Fowler. "It can be built in one-quarter of the time, and its proportionate cost is less. The vessels can be docked and undocked much more easily. Lloyd's will insure a floating drydock at rates as low as graving docks. The difference in cost of upkeep is offset by the additional advantages." Mr. Fowler also drew attention to the floating drydock being constructed by the Grand Trunk Pacific for Prince Rupert. This is to be 610 feet long with 110 feet between towers. The committee appointed the chairman, Mr. Stone, and Mayor Baxter to be a sub-committee to interview the authorities of Canadian Pacific Steamship Service and to ask what will be their share in the establishment of a drydock for Vancouver.

Montreal, Que.—The administration of the St Lawrence ship channel is likely to be attached to the inside service at Ottawa by legislation to be introduced next session. At present it is a part of the outside service. Sir George Murray in his report on the public service suggested direct control from Ottawa of the staff and works, upon which millions are being spent, and it is wholly probable that it will be followed out. There will also be legislation abolishing the pilots' corporation at Quebec, as was recommended by a commission which last winter investigated the pilotage system. Its report came too late to be acted on last session.

Ottawa, Ont.—The application of the Canadian Pacific Railway Company to the Government for authority to increase the company's capital stock by a further issue of shares to the par value of $60,000,000 is likely to be granted. The application has been before the Government since last August, but was not pressed last year in view of the alternative adopted by the company of issuing new stock last fall under the provisions of its charter legislation in regard to stock issues against branch lines. It is understood that the company does not wish to exhaust this method of further increasing its capital stock without recourse to Government sanction, and consequently authority for the next issue will be sought from the Government. Justification for such sanction is urged on the ground that the company is now carrying out a program for main line and general improvements aggregating $100,000,000. It is known that several members of the Cabinet are in favor of granting the application made by the company last August and which has never been withdrawn. Hon. Robert Rogers has frankly stated that he is in favor of Government sanction for the sixty million stock issue. He takes the ground that the greatest need of western Canada is better transportation facilities to keep pace with the rapid development of the country. If the C.P.R. wants to raise sixty million dollars more to spend on the road he sees no reason why the application should be refused.

Toronto, Ont.—A summary of the total expenditure on county roads for the year, according to W. A. McLean, Provincial Engineer of Highways, in his annual report, is as follows:—Road construction, $407,547.90; permanent bridges, $213,162.41; superintendence, $15,764.73; machinery, plant and equipment, $39,946.22; special county grants to townships, towns and villages, $18,821.26; toll roads, $16,830, making a total for the year 1911 of $712,072.52. Provincial grants of one-third of the total expenditure, in accordance with the Highway Improvement Act, amounted to $237,357.50, payment being made during the Provincial fiscal year 1911-12. County expenditure, or the remaining two-thirds, was $474,715. The roads graded, drained and metalled with broken stone and gravel amounted to 240 miles. The expenditure included the construction of 281 tile culverts, 155 other culverts of less than 10 feet span; and 113 bridges of more than 10 feet span. Culvert and bridge construction was all of a permanent type, using concrete tile and corrugated iron for small waterways; principally concrete for culverts of a larger size; and steel and reinforced concrete for bridges, piers and abutments being of solid concrete. Bridge and culvert construction largely proceeds in advance of actual road improvement, as in many cases, the immediate rebuilding of old and decayed wooden bridges on the designated county roads is imperative in the interest of public safety.

Traffic through the American and Canadian canals at Sault Ste. Marie for the 1912 season is recorded as follows: The total freight traffic of both the American and Canadian canals was 72,472,676 tons for the season of 1912, an increase of 36% over 1911. All items of freight show an increase when compared with the season of 1911, except coal, salt, copper and building stone. The total number of passengers was 66,877, a decrease of 13,074, and the passages through both canals numbered 22,778, a gain of 22% over 1911. Traffic through the American canal was 45% of the total freight, 55% of the total net registered tonnage, and 44% of the total number of passengers carried. Through the Canadian canal traffic was 55% of the total freight, 45% of the total registered tonnage, and 56% of the passengers carried.

CANADIAN PRODUCTION OF CEMENT.

The production of cement in Canada during the past few years, though all classed as Portland, has included an output of Puzzolan cement, made from blast furnace slag at Sydney, N.S., and a small production of "natural Portland," made at Babcock, Manitoba, 75 miles southwest of Winnipeg, on the Canadian Northern railway, according to the annual report of mineral production in Canada by John McLeish, B.A.

The total quantity of cement made in Canada during 1911, as per reports received from the manufactures, was 5,677,539 barrels of 350 pounds net each (993,569 tons), as compared with 4,396,282 barrels (769,349 tons) made in 1910—an increase of 1,281,257 barrels, or over 29 per cent.

The total quantity of Canadian Portland cement sold in 1911 was 5,692,915 barrels (996,260 tons), as compared with 4,753,975 barrels (831,946 tons) in 1910—an increase of 938,940 barrels, or nearly 20 per cent.

The total consumption of Portland cement in 1911, including Canadian and imported cement, was 6,354,831 barrels of 350 pounds net (1,112,095 tons) as compared with 5,103,285 barrels (893,075 tons) in 1910—or an increase of 1,251,546 barrels, or nearly 25 per cent.

The cement industry has been rapidly growing in importance, and its output is now exceeded in value amongst non-metallic products by coal and clay products only.

An average of 3,010 men were employed in 1911, the total wages paid being reported as $2,103,838.

The increase in annual production since 1905 has been nearly four-fold. The production per capita in 1911 was about 278 pounds, as against only 79 pounds in 1905. The approximate consumption per capita has increased during the same period from 115 pounds to 310 pounds.

A similar rapid increase in both production and consumption has taken place in the United States, where the annual production now exceeds 75,000,000 barrels.

PERSONAL.

Mr. A. N. BEER has been appointed assistant waterworks engineer of Ottawa, to succeed Mr. Storrie.

Mr. ALEXANDER LARIVIERE, who for some time has been connected with the Montreal Harbor Commission, recently resigned and has joined the staff of the Department of Roads, Province of Quebec.

J. T. HOWARD, B.A.Sc., has become associated with the F. W. Thorold Company, consulting engineers and contractors, as engineer. Mr. Howard is a graduate in structural engineering of the University of Toronto.

Mr. F. T. BOWRING, of Winnipeg, was a visitor at the office of *The Canadian Engineer* this week. Mr. Bowring is on an extended trip through the eastern provinces. He is a member of the municipal engineering firm of Bowring and Logan, Winnipeg.

W. CHASE THOMSON, M.Can. Soc., C.E., has opened an office in the new Birks Building, Montreal, as consulting engineer. Mr. Thomson will make a specialty of bridges and other steel structures. His experience in bridge and structural designing covers a period of twenty-three years, during which time he has spent three years with the King Bridge Company of Cleveland, Ohio; seventeen years with the Dominion Bridge Company, Limited, of Montreal; and the past three years as manager for Canada, with the Cleveland Bridge and Engineering Company, Limited, of Darlington, England. Mr. Thomson has contributed several articles to the engineering journals and has written two books: "Bridge and Structural Design" and "The Design of Typical Steel Railway Bridges," both of which are extensively used, both in colleges and engineering offices, throughout Canada and the United States.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS.

The sixth semi-annual meeting was held at the Engineers' Club in Boston, Mass, June 25-28. Papers were presented on "The Power Plant," by Perry Barker, of Arthur D. Little, Inc.; "Relation of the Manufacturer to the Patent System," by Dr. W. M. Grosvenor; "Depreciation and Obsolescence," by R. K Meade; "Legal Control of Dangers to Health in Factories," by Dr. C. F. McKenna; "Some Peculiar Functions of the Retained Expert," by Dr. W. M. Grosvenor, and other papers.

COMING MEETINGS.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, J. W. H. Watts, R.C.A., Ottawa, Ontario.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Annual Meeting in Regina, September 16, 17 and 18, General Secretary, Major Drum, Ottawa; Local Secretary, Dr. Murray, Regina.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D.C.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, Lo21 Brown-Marx Building Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

NATIONAL ASSOCIATION OF CEMENT USERS.—Tenth Annual Convention to be held in Chicago, Ill., February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Meeting to be held at Lethbridge, Alberta, on August 5th and 6th, 1913. Secretary, Norman S. Rankin, Calgary, Alta

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

19666—June 24—Authorizing C.P.R. to operate trains, engines and cars through the junction and over crossings, at Mile End, Que., without their first being brought to a stop.

19667—June 24—Authorizing C.P.R. to operate trains through junction, and over crossings, at South Junction, Que., without their first being brought to a stop.

19668—June 24—Authorizing City of Hamilton, Ont., at its own expense, to construct extension to Primrose Ave., easterly across spur, of T.H.&B., on Lot No. 6, Con. 2, Tp. Barton, now in City of Hamilton.

19669—June 24—Authorizing C.P.R. to operate trains over interlocking plant at swing bridge over Trent Canal, near Talbot, Ont., without their first being brought to a stop.

19670—June 24—Authorizing C.P.R. to operate trains over interlocking plant at swing bridge, at Couchiching Narrows, near Atherly, Ont.; provided that if distant semaphore is at "Caution," trains must stop and not proceed over it until the same is clear.

19671—June 24—Extending, until Dec. 31, 1913, time within which C.P.R. complete branch line, authorized to be constructed, maintained and operated under Order No. 17075.

19672—June 21—Directing that speed of all trains passing over crossing of Archabail St., St. Boniface, Man., be restricted to four miles per hour; no cars be left standing on S.W. side of crossing closer than main lead switch; and on first track south of main line, on east side of crossing, closer than 75 feet from board walk, on N.W. side of main line, known as Winnipeg Steel Granary Spur; sign posts be erected indicating points where cars must not be left standing outside of sidings, for guidance of those setting cars on tracks.

19673—June 23—Authorizing G.T.R. to construct siding for Collie-Cockerill Manufacturing Co., Ltd., on Lot 79, Con. 1, Tp. of Whitchurch, Co. York, Ontario.

19674—June 24—Amending Order No. 19536, dated June 10th, 1913, by striking out words: "Its appearing that the Railway Company has failed to comply with requirements of said Order No. 15780," in recital of said Order No. 19536, and substituting words, "what was submitted by the Railway Company."

19675—June 25—Approving proposed alterations in C.L.O. & W. Rly. Co.'s railway, so as to include within limits of right-of-way covered by location approved under Order No. 19196, portion of Lot 18, Con. 3, Tp. South Sherbrooke.

19676—June 25—Authorizing C.P.R. to construct switching lead to yard at Smith's Falls, Ont., across road allowance between Cons. 3 and 4, Tp. Montague, Co. Lanark, Ont., at mileage 133.0 from Montreal Jct., Smith's Falls Subdivision, Eastern Div.

19677—June 25—Authorizing C.P.R. to construct Bridge No. 95.6 over North River, Muskoka Subdivision, Ontario Div., Ont., near Lovering Station.

19678—June 25—Authorizing C.P.R. to construct Bridge No. 1.1 on Hamilton Subdivision, Ont. Division, Ontario.

19679—June 25—Amending Order No. 19489, dated June 7th, 1913, by striking out words "Belle Plain," in 4th line of operative part of order, and substituting therefor the word "Pense."

19680—June 24—Authorizing C.N.O.R. to divert public road between Lots 5 and 6, Con. 3, Tp. York, Co. York, Ont, and to construct across said road by means of structure carrying highway over railway.

19681—Juns 21—Directing C.N.R. to construct farm crossing on E. Good's farm on Lot 5, Con. 6, Tp. Nepean, Ontario.

19682—June 21—Amending Order No. 19227, dated May 9th, 1913, by adding following clause: "That the traffic of the Grand Valley Railway Company shall not be interrupted by the work authorized under this order."

19683—June 23—Rescinding Order No. 17386, dated Aug. 28th, 1912, in so far as it approves location of station at St. Gregoire, Que., and approving location G.T.R. station at St. Gregoire, Que., as shown on plan dated June 5th, 1913; said station to be completed on or before Aug. 1st, 1913.

19684—June 21—Directing that Central Ont. Rly. schedule train No. 3, leaving Trenton at 1.45 p.m., to arrive at Central Ontario Jct., to connect with C.P.R. No. 17 due at said Jct., at 3.13 p.m., etc., etc.

19685—June 24—Requiring Que. Oriental Rly. (1) to add to its equipment, not later than Dec. 31, 1913, two new locomotive engines capable of carrying at least 160 lbs. steam pressure to the square inch, and (2) if, after hydrostatic tests, boilers of its present locomotive equipment be found incapable of carrying steam pressure of 160 lbs., company purchase at least four additional boilers for its 17 x 24 inch class of locomotives capable of carrying such pressure.

19686—June 25—Authorizing C.N.R., at its own expense, to construct highway across its railway at McGee Townsite, in N.W. ¼ of Sec. 19-29-16, W. 3 M., Sask.

19687—June 25—Amending Order No. 18048, dated Nov. 11 1913, to provide that curve in road where latter makes right-angled turn just south of track, be constructed so that travelled way shall be 35 feet in width, and extending, until July 15th, 1914, time within which work required to be done under said order is completed.

19688—June 24—Refusing application T.H. & B. Rly. for authority to construct stand-pipe between its main tracks on Hunter St., City of Hamilton, Ont., immediately west of John Street.

19689—June 25—Authorizing Toronto Suburban Rly. to construct across Goderich Branch of C.P.R. a spur into Prison Farm, in Lot Cons. 1 and 2, Tp. Guelph, Co. Wellington, Ont., subject to and upon certain conditions; and rescinding Order No. 19171, dated May 5th, 1913.

19690—June 25—Directing Can. Nor. Que. Rly. to construct raceway and other openings under its railway, on approved location at the Jacques-Cartier River, Lots 79 and 80, Parish of Les Ecureuil Co. Portneug, Quebec.

19691—June 25—Authorizing G.T.R. and C.P.R. to operate trains over crossing on Weston Road, Town of Toronto Jct., Ont., without the first being brought to a stop.

19692—June 23—Approving and authorizing clearances as shown on C.P.R., plans showing clearances at C.P.R.'s new shops, at Ogden, Alberta.

19693—June 25—Directing Brockville, Westport & North Western Ry. Co. to renew ties on following bridges: (a) Just east of Lynn Station; (b) just west of Lynn Station; (3) at Corbett's Creek, new stringers under rails, and (d) over Rideau Canal at Newboro. 2. Company renew at least 30,000 ties on its line; whole line be ballasted; highway crossings be made to conform to Standard Regulations of Board. (3. Work be completed by Nov. 1st, 1913.

19694—June 26—Authorizing G.T.R. to construct branch line and spur therefrom for Beaver Companies, on Lot 48, Con. K, Tp. Thorold, Co. Welland, Ont., work to be completed within three months from date of this order.

19695—June 26—Extending, until Aug. 1st, 1913, time within which G.T.P. Rly. complete work of opening in fill at Cameron Bay, near Prince Rupert, B.C.

19696—June 25—Directing G.T.R., within 90 days from date of this Order, to install electric bell at crossing of John St., in Town of Port Hope, Ont., and thereafter maintain bell at its own expense.

19697—June 26—Authorizing Montreal & Southern Cos. to run trains and cars, with passengers, baggage, express and other traffic carried thereon, over line of Central Vermont Rly., between Montreal & Southern Co.'s Jct., at east end of its Southwark Yards, St. Lambert, Que., and Richelieu, Que., a distance of 12 miles, and to use Central Vermont Co.'s passenger and freight stations, station yards, and other facilities at and between said points.

19698—June 26—Amending Order No. 18997, dated April 8th, 1913, by striking out words and figures: "Calgary Lands Titles Office, on 22nd February, 1913, as Rly. 598," and inserting in lieu thereof words and figures: "Nelson Land Titles Office, on 4th June, 1913, as No. 524, c. 16."

19699—June 26—Authorizing, pending installation interlocking plant, C.P.R., to operate trains over crossing of G.T.R. at Tecumseth St., Toronto, on signals from switchmen; interlocking plant, be installed by August 20th, 1913.

19700—June 26—Authorizing Ansley Coal Co., Ltd., to connect its Ansley Spur Line with spur line constructed for Municipal Corporation of City of Medicine Hat by C.P.R.

19701—June 26—Authorizing C.P.R. to construct two (2) branch lines for Canada Malting Co., Ltd., on S.W. ¼, Sec. 12-24-1, W. 5 M., at Calgary, Alberta. Spurs be completed within three (3) months from date of this order.

19702—June 27—Approving one-way fares shown on page 4 of Montreal & Southern Co. Ry. Co.'s Local Passenger Tariff, C.R.C. No. 3, as maximum tolls to be charged on its line between Montreal and Richelieu and intermediate stations, in Province of Quebec, company to publish same, with copy of this Order, in at least two consecutive weekly issues of "The Canada Gazette."

19703—June 27—Authorizing C.P.R. to construct extension of existing siding along lane between its right of way and Caron Avenue, Windsor, Ont.; spur to be completed within three months from date of this Order.

General Order No. 106—June 27—Amending Order No. 14115, dated July 14, 1911, by adding after clause 5 of Order, following clause: "5a. Boilers equipped with superheated flues. On removal of ordinary flues and of as many of superheated flues as may be necessary for men to get inside of boiler to scale and inspect same, if it is found, upon inspection by mechanical officer in charge at each point where boiler work is done, that condition of superheated flues does not warrant their removal, they may be left in, if thoroughly scaled; said mechanical officer or inspector to be held strictly responsible as provided in clause 2 of the Order."

19704—June 30—Authorizing London Street Ry. and C.P.R. to operate cars and trains over crossing at Adelaide St., London, pending installation of half-interlocking plant—to be installed not later than July 15th, 1913—same to be flagged across by means of day and night watchmen, appointed by C.P.R., at expense of London St. Ry. Co.

19705—June 27—Directing C.P.R. at its own expense to provide and construct suitable crossing where it intersects and crosses Hall St., town of Renfrew, Ont.; said crossing to be constructed in accordance with Standard Regulations.

19706—May 16—Authorizing G.T.P. Branch Lines Co. to construct its Brandon branch across two (2) highways, namely:—1, Mileage 12.14, between Secs. 3 and 10, Tp. 11, R. 17, W. 1 M. and 2, mileage 12.76, between Secs. 3 and 4, Tp. 11, R. 17, W. 1 M.

19707—June 26—Directing that the hours of the watchman at north side crossing of Cherry St., by G.T.R., Toronto, Ont., be extended from 5 o'clock p.m., until 7 o'clock p.m.

19708—June 28—Directing that, upon R. V. MacCosham, Edmonton, Alta., undertaking to comply with Standard Spur Conditions of city of Edmonton, C.N.R. construct branch line, or spur, extending from lots 122 and 123 through lane dividing block 8, to lots 108 and 137.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

▲—Denotes an item regarding work advertised in *The Canadian Engineer.*
+—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

RAILWAYS—STEAM AND ELECTRIC.

Toronto, Ont.—The management announces that the Toronto and Eastern Radial line from Bowmanville into Toronto, will be ready for full operation early next spring. The grade between Bowmanville and Pickering will soon be completed, and nearly four hundred men will be set at work on the grade from Pickering west of Toronto. The steel is already laid from Bowmanville, half a mile west, and a large force of men are now to be placed on laying the steel between there and Pickering.

Vancouver, B.C.—The C.P.R. is making arrangements for the enlargement of the docks at Vancouver, and an extra two hundred feet has been taken over from R. V. Winch & Co. Mr. Peters, general superintendent of the railway, states that the company requires more room on the waterfront for the grain trade.

BRIDGES, ROADS AND PAVEMENTS.

+—Amherst, N.S.—The town council has awarded Mr. J. E. LUSBY the contract for laying cement sidewalks. The contract price was $1.19 per square yard with the town doing the grading and $1.20 per square yard for sidewalks and grading. Other tenders received were:—John Thornton, $1.40 per square yard with the grading and $1.25 a square yard with the town doing the grading; the New England Artificial Stone Company $1.20 a square yard with the town undertaking the work of grading.

+—Brockville, Ont.—The Town council has awarded the A. W. GODSON COMPANY, Toronto, the contract for paving on Perch Street.

▲—London, Ont.—Tenders will be received up till the 31st of July, 1913, for the construction of a highway bridge over the River Thames. Plans and specifications may be obtained from the city engineer, Wm. N. Asphlant.

Medicine Hat, Alta.—The ratepayers of this city have passed a by-law authorizing the expenditure of $75,653 on sidewalks. Mr. A. K. Grimmer is the city engineer.

+—Plairton, Pa.—The DOLARWAY PAVING COMPANY have been awarded the contract for the construction of 12,000 square yards of pavement here.

Ritchat, Man.—Tenders will be received up till the 21st of July, 1913, for the construction of roads in the municipality. Plans and specifications may be obtained from the Highway Commissioner, Winnipeg, and G. T. Landry, secretary-treasurer.

▲—Toronto, Ont.—Tenders will be received up till the 28th of July, 1913, for the construction of a 15-foot span concrete culvert with concrete abutments and reinforced concrete slab. Plans and specifications may be obtained from John Bryan, Esq., Laurel, Ont., and Frank Barker, Township Engineer.

+—Unionville, Ont.—The Highway Board has awarded the LEWIS CONSTRUCTION COMPANY the contract for the erection of the Eckardt bridge. The contract price is $1,466.

Windsor, Ont.—Tenders will be received up till the 29th of July, 1913, for supplying an automatic street flushing machine. Plans and specifications may be obtained from M. E. Brian, City Engineer.

LIGHT, HEAT AND POWER.

▲—Carlyle, Sask.—Tenders will be received up till the 1st of August, 1913, for the supplying power and lighting equipment. Plans and specifications may be obtained from the consulting engineers at Winnipeg and Calgary. F. J. Stent, secretary-treasurer.

+—Cananoque, Ont.—The town council has entered into a contract with the ELECTRIC LIGHT AND WATER SUPPLY COMPANY, for supplying the lighting for the town.

+—Medicine Hat, Alta.—The city has awarded the NORTHERN ELECTRIC COMPANY the contract for installing a fire alarm system. The contract price is $10,840. Other firms tendered as follows: Siemens', Limited, $11,284, (New York); Star Electric, $5,165, plus duty and freight.

+—Toronto, Ont.—The O'Keefe Brewery Company has awarded the TERRY STEAM TURBINE COMPANY, Hartford, Conn., the contract for supplying a 25-horse-power Terry turbine-driven pump.

+—Winnipeg, Man.—The Board of Control have awarded the FORT GARRY CONSTRUCTION COMPANY the contract for the extension to power station. The contract price is $35,800.

+—Winnipeg, Man.—The city has awarded MESSRS. VICKERS, LIMITED, Montreal, the contract for supplying three 5,000 k.w. generators and spare parts. The contract price is $96,318.

Tarvia

Preserves Roads
Prevents Dust~

Beaurepaire Road, Beaconsfield, Quebec. New macadam road treated with two coats of "Tarvia B."

A Splendid Tarvia Highway

THE above photograph shows one of the many fine new roads in the Dominion which have been bonded with Tarvia to give a clean, strong, waterproof surface. The Tarvia work in this instance consisted of a treatment of two coats of "Tarvia B," which is the lightest and the cheapest kind of Tarvia treatment.

At a trifling expense, Beaconsfield thus secured a road surface capable of standing the traffic and needing very little maintenance. The saving in maintenance in itself will balance the cost of the Tarvia treatment. In winter or summer this road will give swift and easy traction. The Tarvia-bonded surface will shed water and the surface will afford good footing.

Progressive communities all over Canada are learning the value of Tarvia as a road preservative and dust layer.

"Tarvia B" requires no heating for application and may be applied from a sprinkling cart at trifling expense. Other grades of Tarvia of greater density and tenacity are "Tarvia X" and "Tarvia A," used in road construction work.

Booklets free on request.

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

GARBAGE, SEWAGE AND WATER.

+—**Assiniboia, Man.**—The municipality has awarded THOS. JACKSON & SONS the contract for the construction of a sub-main from Conway Street to Oakdale Park.

▲—**Bassano, Alta.**—Tenders will be received up till the 15th of August, 1913, for the construction of a sewage disposal works. Plans and specifications may be obtained from the John Galt Engineering Co., Ltd., consulting engineers and Geo. B. R. Bond, secretary-treasurer.

+—**Bowmanville, Ont.**—The town council has awarded Mr. JOHN F. CONNOLLY the contract for a sewage disposal works.

▲—**Carlyle, Sask.**—Tenders will be received up till the 1st of August, 1913, for construction of waterworks. Plans and specifications may be obtained from the consulting engineers at Winnipeg and Calgary. F. J. Stent, secretary-treasurer.

+—**Montreal, Que.**—The city has awarded the JOHN R. McDOUGALL COMPANY the contract for supplying two pumps having a capacity of 12,000,000 gallons. They will cost about $24,000 each. This will bring the pumping capacity of the water department up to about 80,000,000 gallons a day, or about 24,000,000 gallons a day over average requirements.

New Liskeard, Ont.—At a recent council meeting it was decided to call for tenders immediately on the laying of water main extensions and sewers throughout the town and all estimates are now prepared. Nearly 4,000 feet of water main extensions are to be laid during the summer months, while 3,000 feet of sewer will also be installed.

Orillia, Ont.—Dr. J. W. S. McCullough, chief health officer for the province, has notified this town to instal a mechanical filtration plant to treat the supply of water taken from Lake Conchiching.

Oshawa, Ont.—Tenders will be called for in the near future for a turbine pump, 100 horse-power, electrically-driven, 800 gallons per minute. Frank Chappell, Town Engineer and Superintendent of Waterworks.

Oshawa, Ont.—Orders have been recently placed with the Neptune Meter Company, New York City, for additional supply of meters for the town of Oshawa. The metering system of Oshawa has proven very successful. The daily consumption of water has been reduced to 65 gallons per capita. Among the meters used are those manufactured by the Neptune Meter Company, Buffalo Meter Company, Union Water Meter Company, Hersey Manufacturing Company, Gamon Meter Company, Glenfield and Kennedy, National Meter Company, etc.

Point Grey, B.C.—Mr. F. L. Fellowes, city engineer of Vancouver, and Municipal Engineer Johnston, will prepare a joint estimate of the two routes of the partnership water pipe line.

Port Dalhousie, Ont.—The village council plans to install a waterworks and sewerage system. The estimated cost will be $150,000.

+—**Regina, Sask.**—The City Council has awarded the McMANUS CONSTRUCTION COMPANY the contract for laying 12-inch, 10-inch, and 8-inch pipe for the high pressure system.

Toronto, Ont.—Works Commissioner Harris will recommend that tenders be called for the installation of a mechanical filtration plant at the Island, of 60,000,000 gallons capacity per day, in his report that he will make to the city shortly.

Toronto, Ont.—The Department of Works are taking borings to ascertain the geological nature of the bed of Lake Ontario opposite Victoria Park and hydrographic soundings are being prosecuted regarding depth, current, etc., preliminary to the establishment of a filtration plant there.

▲—**Toronto, Ont.**—Tenders will be received up till the 22nd of July, 1913, for the construction of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

▲—**Toronto, Ont.**—Tenders will be received up till the 29th of July, 1913, for supplying portable sewage pumping engines. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

Toronto, Ont.—Tenders will likely be called for by next spring for approximately 2,000 feet of riveted steel pipe to connect the south tunnel shaft with the new mechanical filter plant to be built at the Island.

+—**Victoria, B.C.**—The city council have awarded the following contracts in connection with the northwest sewer system: The GEO. A. POWELL & CO., the contract for supplying 1,500 feet of 2-inch black iron pipe; to MESSRS. E. G. PRIOR & COMPANY, the contract for supplying 3,000 feet of 12-lb. rails and fasteners; to MUSSENS, LIMITED, the contract for supplying 1,000 feet of 8-inch galvanized pipe. These were the lowest bids submitted.

▲—**Victoria, B.C.**—Tenders will be received up till the 31st of July, 1913, for the fabrication and laying of about 10¼ miles of 36-in. riveted steel pipe and appurtenances on the line of the Sooke Water Supply. Plans and specifications may be obtained from C. H. Rust, Water Commissioner.

▲—**Victoria, B.C.**—Tenders will be received up till the 31st of July, 1913, for the laying of about 27½ miles of reinforced concrete pipe and appurtenances on the line of the Sooke Water Supply gravity conduit. Plans and specifications may be obtained from the Sooke Water Supply office, and C. H. Rust, Water Commissioner.

+—**Wingham, Ont.**—The town council has awarded T. J. McLEAN AND COMPANY the contract for storm sewers for the town.

BUILDINGS AND INDUSTRIAL WORKS.

Amherst, N.S.—Tenders will be received up till the 22nd of July, 1913, for the construction of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

Battleford, Sask.—Tenders will be received up till the 31st of July, 1913, for the erection of a public building. Plans and specifications may be obtained from Mr. J. E. Cyr, Winnipeg; Mr. W. T. Mollard, Regina, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Blackstock, Ont.—Tenders will be received up till the 24th of July, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

Brampton, Ont.—Tenders will be received up till the 24th of July, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

+—**Calgary, Alta.**—The School Board has awarded Mr. J. A. McPHAIL the contract for the erection of the Balmoral school. The contract price is $160,000 and the plumbing and heating will be installed at a cost of $28,545.

+—**Calgary, Alta.**—The Sherwin-Williams Paint Company has awarded the CARTER-HALLS-ALDINGER CO. the contract for the erection of a warehouse and store.

▲—**Cochrane, Ont.**—Tenders will be received up till the 22nd of July, 1913, for the erection of an ice house, store house, freight house, and two tool houses. Plans and specifications may be obtained from Mr. Gordon Grant, Ottawa, and Mr. T. S. Armstrong, Cochrane, and the Commissioners of the Transcontinental Railway. P. E. Ryan, secretary.

+—**Collingwood, Ont.**—The Dominion Government has awarded the C. S. BOON DREDGING AND CONSTRUCTION COMPANY the contract for the dredging required here. The contract price is $49,550.

Dalhousie, N.B.—Tenders will be received up till the 21st of July, 1913, for the dredging required here. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—**Fort Carry, Man.**—MESSRS. CARTER, HALLS AND ALDINGER have been awarded the contract for the construction of a swine barn at the new agricultural college. The contract price is $12,718.

Galt, Ont.—Tenders will be received up till the 5th of August, 1913, for the construction of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy-Minister.

Galt, Ont.—The B. F. Sturtevant Company, with head offices at Boston, Mass., will locate a plant in this city. The company manufactures blowers and engines, and is practically the largest industry of its kind in the United States.

+—Kamloops, B.C.—The city has awarded Mr. GEO. McBETH the contract for the agricultural building at the exhibition. The contract price was $10,400. Other tenders received were H. J. Davies, $10,300; R. McKay, $10,395; Fruitlands Building Company, $12,300

+—Lauzon, Que.—The Dominion Government has awarded MESSRS. M. P. and J. T. DAVIS the contract for the construction of the dry-dock. The contract price is $2,721,116.

+—Little Black River, N.B.—The Dominion Government has awarded MR. T. A. FOWLER the contract for dredging. The contract price is $11,095.

Millbrook, Ont.—Tenders will be received up till the 29th of July, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

+—Montreal, Que.—The School Board have awarded Mr. F. HENRI DEMERS the contract for the construction of the Longue Point school. The contract price is $196,000.

+—Montreal, Que.—The Robert Reford Company has awarded the PETER LYALL CONSTRUCTION COMPANY the contract for the erection of the new office building.

Napanee, Ont.—Tenders will be received up till the 30th of July, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

New Westminster, B.C.—On a pile-driver gaily decorated for the occasion, and especially constructed for the carrying out of the first unit of the important scheme, the first pile that marks the commencement of New Westminster's five-million-dollar harbor improvement was driven in place on July 4th.

+—Ottawa, Ont.—A new contract for the Prince Edward Island terminal of the Intercolonial Railway is being considered by the Minister of Railways, the Halifax Dredging Company having forfeited its $75,000 cheque for failure to go ahead with its original contract. It is understood that but one tender has been received and it is that of ALBERT MACKIE of Toronto, associated with M. J. O'Brien. He has the contract for the New Brunswick terminal. The cost of the Prince Edward Island part will be nearly a million.

+—Ottawa, Ont.—The Dominion Government has awarded the SOO DREDGING AND CONSTRUCTION COMPANY the contract for the dredging required at Bruce Mines, Halton and Walker River, Ont. The contract price is $8,832.

+—Ottawa, Ont.—MESSRS. BLACKBURN BROTHERS have been awarded the contract for the erection of a ten-story store and office building. The contract price is $600,000.

+—Ottawa, Ont.—The Dominion Government has awarded the contract for the new dock at Levis to M. P. DAVIS AND SON, Ottawa. The cost is approximately $2,600,000. The drydock will provide accommodation for the repair of the largest ocean liners, thus meeting a long-felt want in connection with the St. Lawrence route. Construction will begin at once, and it is hoped to have the dock in operation for the season of 1915

Ottawa, Ont.—Only one tender has been received by the Government for the new telescope for the Dominion Observatory, that of Sir Howard Grubb, of Dublin. Two sizes of reflecting lenses are under consideration, one of 60 inches and the other of 72 inches diameter, and the cost will be between $50,000 and $60,000. It will take about two years to complete the instrument.

Port Coquitlam, B.C.—Mr. J. D. Taylor, M.P., announced that within a few weeks a contract would be let that would result in a deep waterway up the Fraser River to this point, and that dredging would be finished on this work in time to allow the 200-foot ship now being built at that point to sail on her maiden voyage to the West Indies. As it is hoped to launch this vessel within the next two months the statement made by the member from New Westminster means that within that time the river will be open to ocean carriers as far as Port Coquitlam.

Prince Albert, Sask.—The Imperial Iron and Steel Company will locate a plant in this city. They will create an extensive Western market for scrap iron, while Northern iron properties will be the principal source of raw material.

Revelstoke, B.C.—Tenders will be received up till the 29th of July for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy-Minister.

Saskatoon, Sask.—Tenders will be received up till the 31st of July, 1913, for supplying a motor truck for the fire department. Plans and specifications may be obtained from the Board of Commissioners. F. E. Harrison, mayor.

Saskatoon, Sask.—A company known as the Anglo-Canadian Building and Construction Company, plans to spend $400,000 in the building of dwellings for occupation this fall. They will construct 200 this and 450 similar houses next year. The necessary money is already secured in England.

+—Sault Ste. Marie, Ont.—The Dominion Government has awarded D. JAMIESON AND SON the contract for an electric passenger elevator in public buildings here. The contract price is $11,100.

+—Schenectady, N.Y.—The MACARTHUR CONCRETE PILE AND FOUNDATION COMPANY, New York, has been awarded the contract for the foundation of the new 2,000,000 cubic feet gas holder for the Mohawk Gas Company. About 800 pedestal concrete piles are to be driven.

South Vancouver, B.C.—Public work estimated to cost $21,258 was recommended to the board of works recently by Municipal Engineer Clement, and was approved, subject to the condition that it be carried out under the arrangement whereby the ward expenditure does not exceed $5,000 a month.

+—St. Stephen, N.B.—The Dominion Government has awarded the MARITIME DREDGING COMPANY the contract for dredging. The contract price is $7,935.

▲—Toronto, Ont.—Tenders will be received up till the 25th of August, 1913, for the construction of a sea wall, breakwater, ship channel and retaining walls. Plans and specifications may be obtained from the District Engineer and the Harbor Commissioners, Toronto; H. J. Lamb, Windsor; J. L. Michaud, Montreal; and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Toronto, Ont.—The Dominion Government has awarded Mr. M. SULLIVAN Kingston, the contract for the construction of the new barracks. The contract price is $650,000.

+—Toronto, Ont.—The Canadian Pacific Railway has awarded DENNY BROTHERS the contract for two new steamers for the British Columbia fleet. Each of these is to be 380 feet long by 54 feet beam, and will be required to show a trial speed of 22½ knots. They are to be ready for service by the spring of 1915. They would be placed in service between Vancouver and Pacific ports and Alaska.

+—Vancouver, B.C.—The Rietmore Manufacturing Company have awarded Mr. A. MOIR the contract for the erection of a factory. The contract price is $150,000.

Vancouver, B.C.—Tenders will be received up till the 21st of August, 1913, for the construction of a wharf. Plans and specifications may be obtained from the following district engineers:—C. C. Harsfield, New Westminster; J. S. McLachlan, Victoria; J. L. Michaud, Montreal; and the district engineer, Toronto; the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Victoria, B.C.—Messrs. Rennie and Taylor have awarded MESSRS. PARFETT BROTHERS the contract for the erection of a three-story apartment block. The contract price is $12,000.

+—Victoria, B.C.—The Dominion Government has awarded MR. G. C. HURRELL the contract for the erection of a conservatory building on Gonzales Heights. The contract price was $11,900.

Victoria, B.C.—Tenders will be received up till the 5th of August, 1913, for the erection of eight residences. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffiths, Public Works Engineer.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction of the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

▲—**Windsor, Ont.**—Tenders will be received up till the 29th of July, 1913, for the construction of an incinerator. Plans and specifications may be obtained from M. E. Brian, city engineer.

+—**Winnipeg, Man.**—MESSRS. CRANE AND ORDWAY have been awarded the contract for the plumbing, heating and ventilation system for the new law courts. The contract price is $119,000.

Winnipeg, Man.—Tenders will be received up till the 22nd of July, 1913, for the construction of a dairy barn, poultry building, etc. Plans and specifications may be obtained from the Department of Public Works, Winnipeg. G. R. Coldwell, Acting Minister.

Winnipeg, Man.—Tenders will be received up till the 22nd of July, 1913, for the construction of a residence. Plans and specifications may be obtained from the Department of Public Works, Winnipeg. G. R. Coldwell, Acting Minister.

+—**Winnipeg, Man.**—The Government has awarded THOS. KELLY AND SONS the contract for the erection of new Parliament buildings. The contract price is $2,859,750. Peter Lyall and Sons were the only other tenderers. The building when completed is expected to far surpass all other public buildings in the Dominion and will contain many interesting features. A million dollars in cut stone, will be used in the construction of the walls and towers, while the ground floor and corridors are to be finished in English Portland stone.

CURRENT NEWS.

Newcastle, N.B.—Newcastle is to be the Atlantic terminus of the Universal Radio Syndicate, which will establish a wireless service from Britain to this town as a link in an all-British world encircling service. Land connections have been secured from Vancouver to Montreal, and the company is negotiating for the purchase of existing lines. A Montreal concern has contracted to build and install the plant. The steel tower will be 500 feet high. It is being constructed in England and will be shipped out in sections. Round this central tower will be grouped six other towers, each one hundred feet high, connected by copper wire with the central tower. A dynamo to operate the plant will need a 250 horsepower engine to drive it. The Canadian Government's arrangement with the syndicate is for five years, at the end of which time the Government has the power to take over and operate the service as a Government work.

+—**Ottawa, Ont.**—One of the largest contracts of its kind ever let and one which illustrates the growing use of scientific methods in modern lumbering has been awarded by the MacLaren Lumber Company of Buckingham to VITALE AND ROTHESAY, forest engineers of New York, for a complete cruise and report on the firm's limits along the Lievre. The extent of the limits owned by the MacLaren Lumber Company along the Lievre may be realized when their size is given as between 2,600 and 2,700 square miles. About half of this is virgin timber, never violated by the axe or saw. Mr. Rothesay will make a complete cruise of the limits and will report, not only on the amount of lumber contained therein, but on its qualities of growth and the quantity of lumber which may be cut from year to year and still permit of reproduction. In the old days lumbermen in the Ottawa Valley were notable for their wasteful methods and lumbering was a process of cutting and slashing indiscriminately with no thought to the future. The timber merchant of the present is wiser in his generation and aims to farm his forest wealth, so that it will reproduce itself infinitely, like a crop. Mr. Rothesay, who will direct the work, is a graduate of Yale University and was a classmate of Mr. H. R. MacMillan, head of the British Columbia forestry service, and Mr. G. Piche, who holds a like position in the province of Quebec.

M. E. Storey, manager of the Goulds Pump Company of Canada, Limited, with offices in the Kent Building, Toronto, announces that the name of the company was changed on July 1st, 1913, to the Storey Pump & Equipment Company, Limited. The latter firm will represent the Morris Machine Works of Baldwinsville, N.Y., and Rumsey & Company, of Seneca Falls, N.Y.

Triple Expansion Pumping Engine

FOR WATER WORKS, MINE SERVICE, ETC.

THE Fairbanks-Morse Triple Expansion Duplex Outside Centre Packed Plunger Pumping Engine shown here is very economical in the consumption of steam. The economy of operation makes this Pump preferable to all others in many situations.

¶ The steam end is fitted with semi-rotative valves. The plungers being externally packed are always in sight and any leakage can be at once detected. All parts are easy of access. The stuffing boxes are large and deep, so that an ample allowance of packing may be used.

¶ This type of pump is heavily proportioned throughout in order to meet the demands of heavy service. It is designed to give long and satisfactory service at a minimum cost. It has a 24-inch stroke and a capacity of 2,500,000 gallons per 24 hours.

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned and endorsed "Tender for Toronto Harbour Works," will be received at this office until 4 p.m., on Monday, August 25th, 1913, for the construction of a Sea Wall, Breakwater, Ship Channel and Retaining Walls at the City of Toronto, in the County of York, Province of Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this department and at the offices of the District Engineer, Confederation Life Building, Toronto, Ont.; Harbor Commissioner's Office, 76 Adelaide Street West, Toronto; H. J. Lamb, Esq., District Engineer, Windsor, Ont.; and J. L. Michaud, Esq., District Engineer, Post Office, Montreal, Que.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to five per cent. (5 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, July 12, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—44297.

TENDERS FOR BRIDGE CONSTRUCTION.

Sealed Tenders plainly marked, will be received by the undersigned, up to NOON of MONDAY, JULY 28th, 1913, for the construction of a 15-ft. span concrete culvert with concrete abutments and reinforced concrete slab, opposite Lot 22, Con. VII., Township of Amaranth.

Plans and specifications and all necessary information may be seen at the residence of John Bryan, Esq., Laurel, Ont., or at the office of the undersigned, 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer.

Toronto, July 16th, 1913.

NOTICE TO CONTRACTORS

Sealed proposals will be received at the offices of the Water Commissioners, City Hall, until 12 noon, July 31st, 1913, for the fabrication and laying of about 10¼ miles of 36-in. riveted steel pipe and appurtenances on the line of the Sooke Water Supply pressure conduit, and in accordance with the requirements of the general specifications prepared by Wynn Meredith, Consulting Engineer for such construction, pursuant to the provisions of By-law No. 814.

Plans and Specifications can be seen, and Forms of Tender obtained at the Sooke Water Supply Office, 1414 Douglas Street, Victoria, B.C.

The lowest or any tender not necessarily accepted.

C. H. RUST,
Water Commissioner.

Victoria, B.C., June 27th, 1913.

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on Tuesday, July 22nd, 1913, for the construction of the following sewers:—

Leslie Street, Danforth Avenue to north City limits.
Hastings Avenue, Gerrard Street to Doel Avenue.
Fielding Avenue, Leslie Street to Jones Avenue.
Furniss Avenue, Leslie Street to Jones Avenue.
Fifth Avenue, Leslie Street to Jones Avenue.
Skipper Avenue, Leslie Street to Jones Avenue.
Butternut Street, Jackman Avenue to Ellerbeck Avenue.
Chatham Avenue, Greenwoods Avenue to 554 feet west.
Lark Street, Queen Street to Kingston Road.
Lockwood Avenue, Queen Street to Dixon Avenue.
Pendrith Street, 300 feet east of Shaw Street to 327 feet east.
Lane 1st South Bloor Street, Shaw Street to Roxton Road.
Lane 1st North Queen Street, Triller Avenue to Callender Street.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen and forms of tender obtained at the office of the Commissioner of Works, Toronto.

Tenderers shall submit with their tender the names of two sureties, or in lieu of said sureties, the bond of a guarantee company approved of by the City Treasurer.

The usual conditions relating to tendering as prescribed by City by-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

Toronto, July 8th, 1913.

NOTICE TO CONTRACTORS.

Portable Sewage Pumping Engines.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen and forms of tender obtained at the office of the Commissioner of Works, Toronto.

Tenderers shall submit with their tender the names of two sureties, or in lieu of said sureties, the bond of a guarantee company approved of by the City Treasurer.

The usual conditions relating to tendering as prescribed by City by-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

Toronto, July 7th, 1913.

(For further tenders see pages 86 and 88).

The fire risk

can be materially lessened —and by means that will likely more than pay for themselves through lower insurance rates.

Manufacturers are requested to let us make inspection—without cost—and suggest improvements that will add security against fire. Correspondence invited.

MONTREAL

The Catskill Water Supply of New York City.

History, Location, Sub-surface Investigation and Construction. By Lazarus White, Assoc. Mem. Amer. Soc. C.E., and Division Engineer, Board of Water-Supply. 8vo, xxxii + 755 pages, profusely illustrated with 239 cuts, including figures in the text and full-page illustrations. Cloth, $6.00 net.

Contains a comprehensive view of the whole work and particularly emphasizes the advances and progress made in the design and construction as witnessed by one in close contact with the construction during the whole period.

SECOND EDITION, Revised and Rewritten.

THOMAS-WATT—**The Improvement of Rivers.**

By B. F. Thomas, United States Principal Assistant Engineer, Mem. Amer. Soc. C.E., and D. A. Watt, United States Assistant Engineer, Mem. Amer. Soc. C.E. 4to, 772 pages, profusely illustrated, including many figures in the text, and 83 full-page and folding plates. 2 volumes. Cloth, $7.50 net.

A treatise on the methods employed for improving streams for open navigation and for navigation by means of locks and dams.

RECKNAGEL — **The Theory and Practice of Working Plans.**

By A. B. Recknagel, B.A., M.F., Professor of Forestry, Cornell University. 8vo, x + 230 pages, illustrated, Cloth, $2.00 net.

A book which will assist you in becoming thoroughly conversant with the value and need, scope and sphere of working plans.

HAWLEY-HAWES—**Forestry in New England.**

By Ralph Chipman Hawley, M.F., Assistant Professor of Forestry, Yale University, and Austin Foster Hawes, M F., State Forester of Vermont and Professor of Forestry, University of Vermont. 8vo, xv + 479 pages, 140 figures, principally half-tones, and 2 colored maps. Cloth, $3.50 net.

The Camp-Fire Club of America has awarded to this work their Certificate of High Commendation "as a text-book of value to all interested in scientific forestry."

TENDERS CALLED FOR

THE COMMISSIONERS OF THE TRANSCONTINENTAL RAILWAY.

NOTICE TO CONTRACTORS.

TENDERS FOR BUILDINGS AT COCHRANE.

Sealed tenders addressed to the undersigned, and marked on the envelope "Tender for Buildings at Cochrane," will be received at the office of the Commissioners of the Transcontinental Railway, at Ottawa, Ont., until twelve o'clock noon of the 22nd day of July, 1913, for the erection of an Ice House, Store House, Freight House, and two Tool Houses at Cochrane, Ontario.

Plans and specifications may be seen and full information obtained at the offices of Mr. Gordon Grant, Chief Engineer, Ottawa, Ont., and of Mr. T. S. Armstrong, District Engineer, Cochrane, Ont.

Tenders must be made on the forms supplied by the Commission, and be signed and sealed by all the parties to the tender, and witnessed, and be accompanied by an accepted cheque on a chartered Bank of the Dominion of Canada, payable to the order of the Commissioners of the Transcontinental Railway, for a sum equal to ten per cent. (10%) of the amount of the tender.

The right is reserved to reject any or all tenders.

By order,

P. E. RYAN,
Secretary.

The Commissioners of the Transcontinental Railway.
Dated at Ottawa this 24th day of June, 1913.

Newspapers inserting this advertisement without authority from the Commissioners will not be paid for it.—44403.

TOWN OF CARLYLE, SASKATCHEWAN.

WATERWORKS AND ELECTRIC LIGHTING.

Sealed tenders, addressed to the undersigned, will be received up till 18 o'clock on Friday, 1st August, 1913, for the following contracts:—

1.—Construction of brick power house and concrete reservoir, and laying approximately 800 lineal feet of pipe in trenches, and relative works.
2.—Supply of Air-lift Pumping System.
3.—Supply of Duplex Steam Pump.
4.—Supply and erection of two H.R.T. Boilers and Stack.
5.—Supply and erection of compound vertical steam engine.
6.—Supply and erection of Generator, Exciter, and Switchboard.
7.—Supply of poles, arms, hardware, copper wire, transformers and meters.
8.—Supply of Series Tungsten street lighting apparatus.
9.—Erection of Pole Line.

Tenders must be accompanied by an accepted cheque for five per cent. of the amount of the tender, or alternatively by the bond of an approved guarantee company.

Plans and Specifications and other information may be obtained at the offices of the Consulting Engineers at Winnipeg and Calgary. A deposit of $25 will be required on Contract No. 1, which will be returned to bona fide tenderers on return of the plans.

The Corporation do not bind themselves to accept the lowest or any tender.

F. J. STENT,
Secretary-Treasurer,
Carlyle, Sask.

The John Galt Engineering Co., Limited,
Consulting Engineers.

TOWN OF BASSANO, ALBERTA.

SEWAGE DISPOSAL WORKS.

Sealed tenders, addressed to the undersigned, will be received up till 18 o'clock on Friday, 15th August, 1913, for all labor and materials (except filter distributors) necessary for the construction of sewage disposal works, consisting of tank and filter and relative works near the town of Bassano.

Tenders must be accompanied by an accepted cheque for five per cent. of the amount of the tender, or alternatively by the bond of an approved guarantee company.

Plans and specifications and other information may be obtained at the offices of the Consulting Engineers at Winnipeg and Calgary, on deposit of $25, which will be returned to bona fide tenderers on return of the plans.

The corporation do not bind themselves to accept the lowest or any tender.

GEO. B. R. BOND,
Secretary-treasurer, Bassano, Alta.

July 1913.
The John Galt Engineering Co., Ltd.,
Consulting Engineers.

TENDERS WANTED.

Sealed tenders addressed to the undersigned, marked Tenders for "Incinerator," will be received up till 4 o'clock in the afternoon of the 29th day of July, 1913, for supplying all labor, tools, and machinery for the construction of an incinerator of a capacity to dispose of at least 25 tons per day of garbage and refuse. Incinerator must also be capable of destroying all kinds of refuse, including night soil and dead animals.

Contractors must supply their own specifications and designs, including brick or reinforced concrete building.

A marked cheque for 10 per cent. of amount of tender must accompany each tender, made payable to the order of the City Treasurer, which cheque will be subject to forfeiture in case of failure on the part of the successful tenderer to enter into a written agreement and bond with the City of Windsor with approved sureties when called upon to do so.

Incinerator must be guaranteed for at least one year from date of operation.

The lowest or any tender not necessarily accepted.

M. E. BRIAN,
City Engineer.

Windsor, Ont., July 3rd, 1913.

EXTENSION OF TIME.

CITY OF VICTORIA, B.C.

Sealed proposals will be received at the offices of the Water Commissioner, City Hall, until 12 noon, July 31st, 1913, for the fabrication and laying of about 27½ miles of reinforced concrete pipe and appurtenances on the line of the Sooke Water Supply gravity conduit, and in accordance with the requirements of the general specifications prepared by Wynn Meredith, Consulting Engineer, for such construction, pursuant to the provisions of By-law No. 814, and adopted by the Council.

Plans and Specifications can be seen, and Forms of Tender obtained, at the Sooke Water Supply Office, 1414 Douglas Street, Victoria, B.C.

The lowest or any Tender not necessarily accepted.

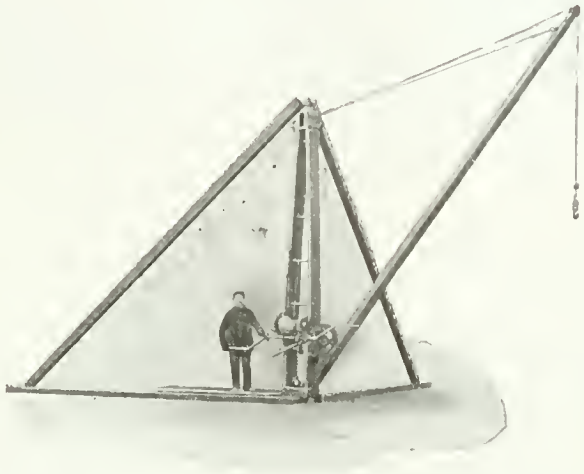
C. H. RUST,
Water Commissioner.

Victoria, B.C., June 14th, 1913.

(For further tenders see pages 84 and 88).

BEATH SCOTCH DERRICKS

Hand or Power



THE construction of Beath Scotch Derricks embodies several points of merit not found in other makes.

All stress parts are **steel,** not cast iron. Bottom Pintle Bearing is of ball and socket type and works in a bath of oil, thus ensuring an easy movement at this joint.

Beath Derricks are provided with self-oiling bearings, ensuring easy operation and reducing wear to a minimum.

We also make Jinniwink Derricks, Stiff Leg Derricks, Guy Derricks, and Steel Derricks for heavy service. Hand or Power operated.

Send us your enquiries for Derricks

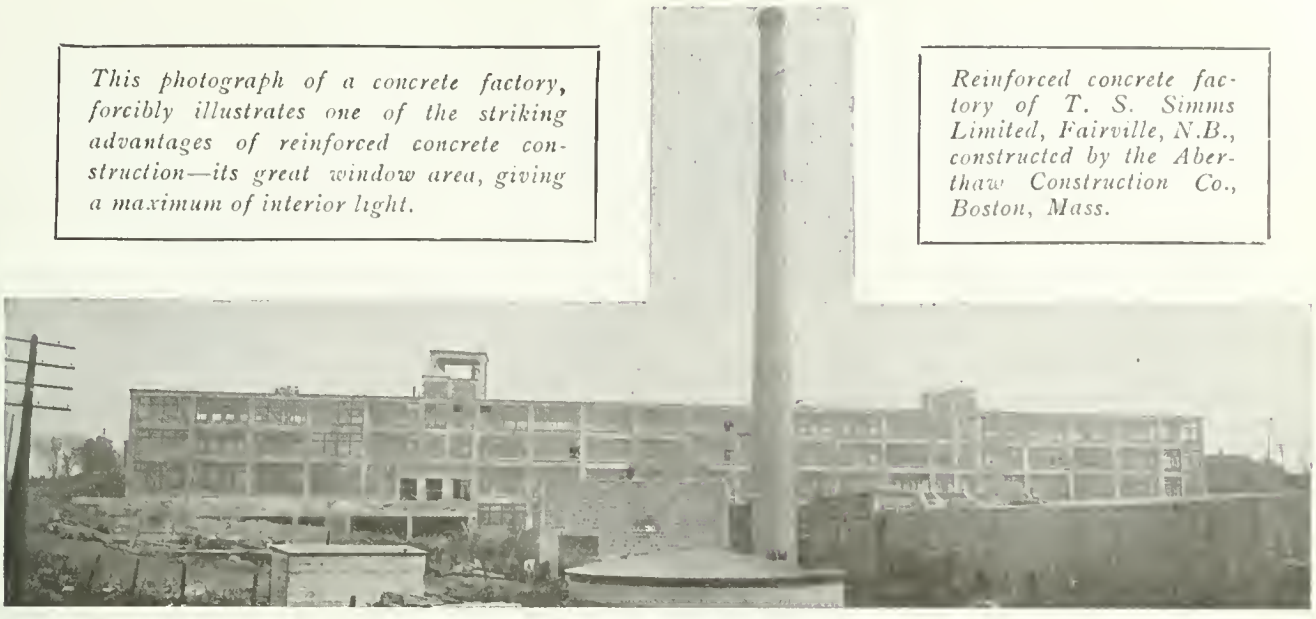
This photograph of a concrete factory, forcibly illustrates one of the striking advantages of reinforced concrete construction—its great window area, giving a maximum of interior light.

Reinforced concrete factory of T. S. Simms Limited, Fairville, N.B., constructed by the Aberthaw Construction Co., Boston, Mass.



Concrete Factories are Most Efficient

The efficiency of a machine is the ratio of the amount of work a machine does, to the amount of work required to operate it. The output is equal to the input minus the work lost or wasted. The less wasted the greater the efficiency.
In the same way the efficiency of a factory may be defined as the ratio of output to input. Output, financially, is increased by reducing unnecessary expenses.

Concrete Stops Wastes

Concrete buildings are proof against fire, water and vermin. They give the maximum light and are sanitary. They resist vibration, and are permanent and durable.

Fire-proofness reduces insurance rates. Water or liquids used in certain processes will not leak through floors to destroy valuable goods below. Rats and other vermin find no place to live in a concrete building, thus eliminating losses from this cause. Maximum light and sanitary conditions increase efficiency of employees. Lack of vibration reduces wear and tear on machines. Permanency and durability reduce depreciation.

The way in which concrete stops these leaks is fully described in our handsomely illustrated 224 page book, "Factories and Warehouses of Concrete." It contains photographs and data of factories and warehouses for all classes of industries.

OUR EXPERIENCE of many years standing, combined with our up-to-date **PLANT** and our complete **ORGANIZATION** insures

SPEED EFFICIENCY ECONOMY

MARKET CONDITIONS

Montreal, July 12th, 1913.

Prices hold very steady, being again unchanged, as follows:—

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is unchanged, being now per 100 lbs., as follows:—¼-in., $5.30; 5-16-in., $4.70; ⅜-in., $3.90; 7-16-in., $3.65; ½-in., $3.55; 9-16-in., $3.45; ⅝-in., $3.40; ¾-in., $3.35; ⅞-in., $3.35; 1-in., $3.35.

Copper.—Prices are 16¾c. Excellent demand.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c, and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dyoamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are: Queen's Head, $4.35; Colborne Crown, $4.25; Apollo, 10¾ oz., $4.25. Add 25c. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lead.—Prices are firm at $5.35.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft. x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is active and strong:—$36 for 6 and 8-inch pipe and larger; $37 for 4o-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per ceot. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 73½ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73½ per cent. for black and 63¼ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, July 16th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton. Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is higher at 16 to 16¼c., sheet copper case (16 oz. soft), 22¼ to 25¼c per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound, 1 to 0-case lots, 50 lbs to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 5c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 5c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable eoquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.50 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—23c. per lb

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.20; 22-24, $3.35; 26, $3.50; 28, $3.95; 29, $4.25; 10¾, $4.25 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 50 to 52c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6.50 to $8 per cwt.

Winnipeg, July 15th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c.; anvil and vise combioed, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ¾, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge Americao, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

An Engineering Weekly

SOME NOTES ON MACADAM ROADS AND PAVEMENTS

MODERN NECESSITIES FOR VARIED HIGHWAY TRAFFIC—NEW DESTRUCTIVE FORCES AND AGENCIES TO MEET THEM—PAVING MATERIALS AND THEIR CHARACTERISTICS

By FRED. L. MACPHERSON, A.M. Inst. C.E., A.M. Can. Soc. C.E.,

Municipal Engineer, Burnaby, B.C.

Of paramount interest to any public body is the vital and far-reaching question of transportation. Next to transportation by rail and water, comes transportation by road—the one being the logical outcome and veritable necessity of the other. Railways are first in the early development of any country, but without a comprehensive system of trunk highways as feeders to the railways further development of the country is hampered and progress impeded. Recently there has been a revival of the road-building problem and the "Good Roads movement" is receiving the attention it deserves, not only from municipal bodies and provincial and federal authorities, but also from the general public. Good roads are essentially a business proposition; commercial, industrial, agricultural, and social conditions are all directly or indirectly benefitted by them. They are not only an index of, but also a means towards, a country's greatness and prosperity. They result in the cheapening of transportation, improved marketing facilities, increased land values, and the betterment and extension of social conditions and privileges. Much has been said about the indifferent agricultural conditions existing in the Fraser Valley districts. Obviously enough, the remedy lies in providing more and better transportation facilities by road. Railways and car lines, while materially assisting, do not, and cannot, in themselves supply the largely felt needs of cheap, speedy and effective transportation direct between our fruit and dairy farms and our towns and cities. Increase our mileage of roads, improve our existing roads, afford our farmers and fruit-growers an opportunity to compete on equal conditions with fruit-growers, and not only do we decrease the high cost of living, but we also prosper and populate our fertile fruit and farm lands. Assuredly development and progress will go hand in hand with the provision for better means of highway transportation. Due stress has been laid on *good* roads. The roads which were good enough a few years ago are now indifferent, some of them even bad. With the drastic change in traffic conditions the former methods of construction of arterial highways are either materially changing or fast becoming obsolete. The time is at hand when country roads will be subjected to as heavy traffic conditions and as severe usage as are city streets. Country roads, being generally narrow and highly crowned, the traffic is concentrated on the central portion of the roadway, whereas on the wide city street the traffic is scattered, conditions which are further aggravated by the greater speed allowed on country roads than on city streets. In view of such facts, and in the very force of circumstances, it seems natural to conclude that the same care, discretion and skill which is now exercised in the designing and construction of city pavements should also be extended to the planning and building of the much-travelled main highways. The problem at issue, therefore, appears to be the construction at a reasonable cost of a modified paved highway which will combine the utility and durability of the paved street and yet retain the aesthetic and attractive features of a rural road.

Few, if any, of us wish to see our rural highways converted into the stereotyped paved street, for apart from their mere utilitarian objects there is much that is naturally attractive and appealing to the motorist and pleasure seeker in the ordinary rural highway, with its straight, level stretches, joined by easy, graceful curves, succeeded by undulations peculiar to a rolling country. The conception and construction of the more modern highway should, therefore, be along lines both utilitarian and aesthetic. To develop a highway which will ultimately fulfil all of its requirements one should be governed by the following principles: (1) The building of a road in the best possible location as to line and level. (2) The macadamizing of the road of suitable width and depth. (3) The conversion of such road with a consolidated rock foundation into a bituminous pavement by hard surfacing. Desirable and necessary as paved roads may be, it is not financially possible for most municipal authorities to undertake at the outset a large mileage of permanent roads at a higher first cost. But arrangements can generally be made for the construction at reasonable cost of a good paved road in the above successive steps.

In commenting on roads and pavements, it is natural to first discuss the former and its relationship to the latter. Road or street construction has gone through a period of evolution—the modern paved street of to-day being the logical outcome of the roads of yesterday, just as the modern macadam road has replaced the trails of the pioneer and the prospector of earlier days. Increased traffic, the easy and economical transportation of heavy loads, consequent upon the settlement of the country, made necessary the convertion of the first rough trails blazed through the forest, into passable thoroughfares.

Passable thoroughfares stood the demands of traffic and served the immediate needs of the earlier settlers, but with the rapid development of the country, and the upgrowth of townships and communities, the need for better highways of communication became not only necessary but imperative. A district settled up just as fast as the means of communication were extended, and developments kept pace with the road improvements. In short, roads came before towns and cities, and not until the townships developed into cities by easy stages and through many vicissitudes, did the modern city street as known to us arise and become standardized. In short, good roads and streets and higher civilization go hand in hand, each being interdependent on the other.

Macadam Road Construction.—In treating of macadam roads it is necessary to distinguish between water-bound macadam roads and bituminous-bound macadam roads. The former have been in adoption for about a century, and although the present methods employed in building water-bound macadam roads are entirely different, owing to the introduction of labor-saving devices, the principles underlying their construction are essentially the same. The first requisites for macadam road construction, namely, drainage, compactness of sub-grade, selection and grading of materials and consolidation of whole, are the same to-day as they were in the pioneer days of road building. The scientific, though commonplace, principles underlying the successful construction of the water-bound macadam road are:—

(1) The compression and compacting by rolling of the different sizes and shapes of broken stone (varying from foundation upwards) by knitting together and interlocking the rough angular surfaces of the stones.

(2) The application thereto by further rolling and sprinkling of a binding course of suitable material to cohere the whole, reduce the voids to the minimum and rended the surface as wearing and as waterproof as possible.

Recognizing such fundamental principles it is not difficult to realize that the satisfactoriness and serviceability of a water-bound macadam road are principally dependent on the preservation intact, and as nearly as possible waterproof, of the wearing surface. The disintegration of water-bound macadam roads is, therefore, chiefly due to the ravelling action consequent upon long spells of drought which dries up the binding material, diminishes its cementing action and lays the aggregate underneath at the mercy of the destructive action of traffic.

The Effect of Speedy Vehicles.—The action of iron tires on slow-moving vehicles was not so severe on, and destructive to, such water-bound macadam roads, and with eternal vigilance necessary repairs could be made at comparatively small expense to keep such road in ordinarily good condition, and with further precautions of scarifying and resurfacing of such roads every two or three years they could generally withstand the ordinary wear and tear of traffic. The forces to which the roads were then subjected were strictly dead and live loads and of course impact, due to action of horses' hoofs and bumping of wheels in ruts and depressions. The speed at which vehicles then travelled being moderate, the live load on the roads was not then so appreciable and the impact not very high. Hence, water-bound macadam roads achieved their precious ends in successfully withstanding such physical forces. There was thus no immediate necessity for any better class of highway to accommodate the travelling public who were at that time generally satisfied.

But with the introduction of the automobile in the last decade, conditions entirely changed and engineers and authorities were confronted with the more serious problem of preserving the surface of the roadbed from the disintegrating and ravelling action of swiftly moving rubber-tired automobiles. The former methods of construction of water-bound macadam roads had necessarily to give place to the adoption of bituminous-bound macadam roads, the second stage in the evolution of the more modern hard-surfaced highway. Not only had the roads then to meet forces due to dead load, live load and impact and all these in a greater intensity, but also the more destructive and disintegrating forces of suction and shear.

Suction is the indirect result of the wind current and vacuum formed at the rear of the tires of a swiftly moving automobile. Such a force, or the resultant of such forces, tends to break the bond, loosen and disturb the binding particles in the surface of the road, and ultimately to disintegrate the roadbed.

Shear is caused by the tractive force exerted by the driven wheels of an automobile and naturally its intensity varies directly with the weight and speed of the automobile. Such a force has also a disintegrating effect on the surface of the roadbed. Since water-bound macadam roads have little or no resistance to the above action of suction and shear, it can readily be seen that it is imperative to build a road with binding material sufficiently strong and cohesive.

The more general use of the automobile also emphasized and increased the dust nuisance, so that attention had to be devoted to the dual problem of the preservation of the wearing surface, and the prevention or elimination of the dust. Various methods of applying different kinds of oils and emulsions, at different degrees of temperature, and under different conditions, have been adopted to bind together and consolidate the rock aggregate of the roadbed, and to abate, if not entirely eliminate, the dust nuisance. While many such preventive methods have met with a measure of success, they cannot be said to be generally and wholly satisfactory. While engineers and road experts are to be congratulated on the skill, ingenuity and resourcefulness, which they have adopted in their determined efforts to construct a bituminous macadam road, at low first cost, of passing serviceability, to meet the new problems associated with the changes of highways traffic, it cannot be justly maintained that the remedies, taking the all-important factor of maintenance into account, have been permanent.

Road Treatments. — The various "treatment" methods in vogue have afforded a temporary measure of relief, but as their ultimate success depends on frequent treatment, they are at the best only make-shifts, and costly at that. Referring to the oiling of roads, this was first adopted in California, where the local residual oils were used to counteract the destructive influences of the long drought on water-bound macadam roads, for while generally speaking water-bound macadam roads are not adapted to a humid climate, such as portions of the Pacific Coast, they are equally unsuited to such a dry climate as California. As already stated, a certain amount of moisture and dampness is necessary to keep the binding materials intact. The highest authorities agree that the best oil to adopt is a pure oil, unmixed with any other oils, and one having a natural asphaltic base. It is the asphaltic properties in road oils which, mixed with the aggregate or injected into the roadbed, binds the materials together and hold them in place, thus pre-

venting, or at least reducing, the ravelling of the roadbed. The best results are produced if a heavy road oil is used after the road has been partially rolled and previous to the laying of the binder course of fine rock or coarse sand. In this way the asphaltum in the oil gets thoroughly incorporated with the component parts of the roadbed which are bound together and interlocked. Successful results have also been achieved in mixing the rock and asphaltic oil together in an ordinary concrete mixture before laying it down. The application of from one-third to one-half gallon of road oil per square yard to the wearing surface of an old macadam road tends to preserve it from wearing action and renders the surface more even and waterproof and incidentally lays the dust. But such measures are merely palliatives and dust preventives, comparatively cheap to adopt (2 cents per square yard or $150 per mile for a width of 12 feet) and, moreover, a decided relief to the travelling public and householders during the summer months. With the approach of the wet seasons, however, the roads thus oiled are rendered muddier than ever, and the mud, being of a heavy, plastic nature, is more difficult and costly to remove. The results from surface road oiling are subsequently disappointing and there appears to be something in the contention that the oiling of roads, while preserving the surface in summer, tends to loosen and disintegrate the particles of the roadbed in winter when they are subjected to the trying alternating influences of rain, frost and thaw. Hence, after several seasons of experimenting with surface oiling with different conditions, such as sweeping the roadbed free of all dust and dirt, applying the oil by means of spraying machines under pressure, and in adopting every conceivable device to arrive at the most satisfactory results, the practice of road oiling has been abandoned by many authorities as being too costly.

In their determined efforts to preserve and lengthen the life of macadam roads and to combat the dust, nuisance engineers and authorities have been experimenting for several years back with coal tar in the building of tar-macadam roads. Refined coal tar from gas works, specially treated to remove the injurious constituents and yet to preserve the ductile and bituminous properties of the tar, has been generally employed in the construction of such roads. The methods adopted have varied considerably, but the general principles of construction involve the heating of the stone to drive out the moisture and the mixing by hand or mixer of the stone, and tar heated to a specific temperature. The chief drawbacks to the use of tar on construction of macadam roads are:—

(1) It is difficult to procure commercial tar of uniform quality.

(2) Great care is necessary in the heating of tar, for if heated too much it becomes brittle and loses its ductile properties upon which its virtue depends.

(3) The tar must be uniformly refined—if refined too little the light volatile oils and ammonia will disintegrate it, if refined over much it will be too brittle.

(4) The weather must be warm and dry to successfully use tar macadam.

(5) The roadbed must be perfectly clean and dry. Hence the use of tar-macadam is confined to the summer months.

(6) It is too susceptible to extremes of temperature, being soft and mushy in midsummer heat and too brittle and slippery in cold, frosy weather.

(7) It is not sufficiently dense and durable.

Better results appear to have been procured from tar-macadam roads in the Old Country, probably because of the more uniform and better quality of commercial tars which are there procurable, and also owing to more careful and scientific construction. In this country their adoption has been confined chiefly to eastern cities, where it has been found that, at an average cost of about 50% over the cost of ordinary water-bound macadam roads, fairly satisfactory and serviceable results have been procured for the first two or three years, but that after that period the wearing surface began to develop a mottled appearance and to disintegrate. Tar painting of such broken surfaces to seal the pores and preserve the surface has been tried but without the desired results, and consequently recourse has been had to covering such tar-macadam roads, on which the foundation is good, with a sheet asphalt or some other asphaltic mixture preparation. Hence, owing to the varibility of the results produced, and the shortness of the life of even the best tar-macadam roads, their further adoption has been generally abandoned in favor of some more durable bituminous pavement of greater first cost. The general failure of the use of commercial coal tar led to much experimenting and the result has been the production of a specially distilled coal tar preparation known as "Tarvia." But while its use, when confined to park roads and boulevards, has met with a measure of success, it cannot be maintained that the results produced on its adoption to much-travelled highways has justified its additional cost. As applied to the road surface as a dust preventive, its average cost is 10 cents per square yard, or about $825 per mile for a 14-foot roadbed, and while further treatment can be applied at a correspondingly less cost, taking the cost of periodical treatments into account, it cannot be said to be economical in the long run. Briefly, the process consists in applying to the ordinary macadam formation, under a pressure of about 50 lbs., heavy asphaltic oil containing about 85% of pure asphalt and heated to a temperature of about 220°. The macadam is laid and rolled in two courses; the first course consisting of about 6 inches of 3-inch sized rock, and the second course varying in size from 1-inch to 2-inch rock. To this latter course is applied the heated asphaltic oil, which penetrates throughout the whole of the macadam. On top of this oil is spread a layer of granite screenings varying from ¼ inch to ¾ inch, from which the dust and dirt have been eliminated and the whole mass is then thoroughly consolidated by rolling. Another treatment of oil is then applied, and further granite screenings about 3/16 inch spread and rolled. Judging from results, such an asphaltic treatment appears to produce a compact, elastic roadbed, with a smooth surface of beautiful appearance. While the experiment has only been of comparatively short duration and it remains to be seen whether or no its durability will be proved, the additional cost of about 25% over the ordinary water-bound macadam road fully justifies its more general adoption. It is estimated that such an "oilcrete" road would wear well for about five years, and as it eliminates the need for yearly oiling of an ordinary macadam road, whose life at the most is three years, there is much to be said in its favor.

It will serve no purpose to discuss further any of the other oils, bitumens and special preparations which the ingenuity of engineer and manufacturer have devised in their endeavor to meet the special requirements of this automobile age. Although each manufacturer or inventor claims his particular preparation to be the panacea of road construction, their compositions are all very similar and the methods of use and application vary only slightly.

Reference, however, should be briefly made to an entirely different product, known as "Roc-mac," a solution which has recently been adopted with considerable success in this country after having withstood satisfactory tests in Great Britain. In use it differs essentially from other binding materials inasmuch as its action is purely chemical, whereas the action of the others is more physical. Roc-mac solution is a patented substance which unites chemically with limestone screenings to form a carbonate compound of good binding and adhesive qualities. No heating of any of the materials is required, nor is any special plant necessary for its use. It can be laid during almost any kind of weather and is not greatly affected by extremes of temperature or by weather conditions.

Reference to the above preparations shows that engineers and road experts have been fully alive to the situation, and are confronted with problems which, although seemingly more commonplace than the design and construction of bridges and other structural works, are yet more complex and difficult of solution. In road construction it is a vital matter these days to change with changing circumstances; for instance, road builders had scarcely adjusted themselves to the changed conditions brought about by the swiftly moving automobile, and made what was then considered adequate provision for their requirements, when the motor truck was introduced to further complicate the problem of the construction and maintenance of roads. They are now face to face with a situation which demands not merely remedial measures, but some more or less permanent cure. The motor truck has come and come to stay; the number is certain to increase and multiply, particularly in interurban districts, and the type of road which their heavier and more rumbling loads and their greater impact necessitate, must be built, and built to wear. Neither water-bound nor bituminous macadam roads will, for any length of time, withstand the intensive and irregular stresses produced by heavily loaded and moderately speeded motor-trucks. While the foundation of the ordinary macadam roads, particularly where they have been gradually built-up with periodical resurfacing, is likely to be sufficiently strong and rigid, it is imperative that such a foundation be kept intact from the impounding action of motor trucks by means of a sufficiently thick, durable and waterproof surface. Road authorities are consequently turning their attention to the construction of a modified form of city pavement for use on the principal highways.

Advantage of Pavements.—That good street pavements are essential to the highest development of the commercial, sanitary, social and educational life of any city cannot be disputed. To any city or town they are an asset which cannot be computed in mere figures. The hall mark of any city is its good pavements, which attract and impress not only the casual visitor, but the manufacturer or investor bent on introducing industries or investing capital. Pavements are part and parcel of the everyday life of the merchant, the manufacturer and the private citizen—all of whom are affected financially and otherwise according as the pavements are good, bad or indifferent. The beneficent and far-reaching influence of pavements upon the social, aesthetic and commercial life of any community cannot be enlarged upon within the scope of this paper, but briefly the principal advantages derived from the construction of pavements are:—

(1) Tractive power is diminished and the cost of transportation correspondingly decreased—benefits accruing alike to commerce and business.

(2) The fixing of a permanent grade and building line permitting of permanent and uniform improvements to buildings, residential and commercial, fronting on the street—chiefly private benefits.

(3) Increased efficiency of fire protection afforded by the better transportation of fire-fighting apparatus—benefits to the community at large.

(4) Enhanced values of property abutting on streets.

(5) The beautifying of the street through having a regular and uniform appearance as to lines and levels—chiefly aesthetic benefits.

(6) The more efficient sanitation and cleanliness and resultant healthfulness, the dust and mud problem being to a great extent eliminated—sanitary benefits.

(7) The furtherance of pleasure driving and thereby the promotion of social intercourse—community benefits.

In short, on business streets, good pavements are an indispensable necessity to good business and commerce; on residential streets they naturally add to the comfort, pleasure and health of the community. Reference was made to *good* pavements as it cannot be contended that any or all classes of pavements confer the above benefits on the life of public and private citizens. The next important question is, therefore, the selection of a type of pavement which will meet with the special requirements of the location and be suitable for the purposes to which it is to be more particularly put. This selection of a pavement is a contentious matter upon which divergent opinions obtain, depending upon whether they are looked at from the standpoint of the individual property owners, the manufacturers or promoters of the pavement, and last but not least the standpoint of the engineer in charge. As the bulk of the paving work in cities is done under local improvement, the determination of the kind of paving material to be used lies almost wholly with the property owners, the opinion of the majority of whom must prevail. This system is, therefore, open to criticism and tends to abuse of privileges as it means that the whims of property owners are assented to and a class of pavement laid on an objectionable layout which is frequently not suitable from an economic or engineering standpoint —being cheap in first cost, or entirely unsuited to the grades of the street. Utilitarian, not sentimental, principles should be given first consideration. The adoption of a type of pavement best adapted to the city as a whole or to any particular kind of street is frequently entirely overlooked. No particular type of pavement is equally adapted to meet the requirements of all cities, nor is any one kind of pavement suited to all the streets in the same city. The needs of each city should be specially studied, just as the needs of each street in any city should receive particular attention. The present and prospective uses of the street, the relative location to existing pavements, the traffic conditions, present and probable, the nature and kinds of materials available, the nature of the subsoil, the cross and longitudinal grades—all these are highly important factors to be considered in determining the best pavement to be adopted for any particular street. Commonplace and commonsense as are all of such matters, infrequently they are either wholly or partially disregarded.

The most important factors which should govern the design of city pavements, are those affecting the health and comfort of the citizens in eliminating, as far as possible, the nuisances arising from dust, noise, odors and slipperiness. While it is generally conceded that the best, most durable and latterly the most economical type of pavement to lay on steep grades of business streets is

rough granite or whin block, its use is limited to such physical conditions on account of its noise and its roughness to automobiles and pleasure vehicles, and its destructive effects on horses' hoofs. Asphaltic mixture pavements, on the other hand, are noiseless, practically dustless, and afford easy and pleasant locomotion, but in wet and frosty weather many types of this pavement are slippery, particularly on average grades, and are therefore unsuitable for heavy teaming traffic.

Such instances emphasize the need for care and discretion in the selection of a class of pavement to be adopted in any city street—conditions which at best only require the exercise of commonsense judgment.

Width of Pavements.—This is an important feature of pavements, which is frequently lost sight of in designing city streets. Neglect of fundamental principles in the adjusting of the width of the pavement often gives rise to subsequent widening and reconstruction at heavy expense. Purely residential streets and business streets should be treated on their own merits and semi-residential streets destined to become business streets should have special consideration. Traffic conditions present and prospective should always be duly considered, as not infrequently an important street will subsequently be selected because of its preferable grades or location for a car line and unfrequented thoroughfares may become business streets owing to the location of works or factories, or railway and dock terminals. An excessively wide pavement on a residential street is an unnecessary and extravagant expense inasmuch as it is expensive to maintain and clean, while a narrow pavement on, say, a car line street is a source of danger and tends ultimately to congestion of traffic, and resultant financial loss to the travelling and business public. In residential streets primary attention should be paid to aesthetics; in business streets the study of traffic conditions should have first consideration.

Construction of Pavement.—Next in importance to the selection of type of pavement is its construction. The permanent value of any pavement, be it of the poorest type, depends to a very great extent on the discriminating selection of the materials which form the component parts of the pavement, and the care, efficiency and thoroughness used in the grading or mixing of materials, and in the actual laying down of the pavement. In paving, as in any other class of construction, the greatest stress should be laid on the studied and systematic attention to the all-important details, and the necessity for taking pains, as close, careful and scrutinizing inspection is necessary right from the drainage and preparation of the subgrade to the finishing touches on the wearing surface. Instances are known to us all of the best types of pavement turning out poor and unsatisfactory just because of carelessness in construction, or laxness and indifference in inspection, while many comparatively poor types of pavement often stand the test of time and traffic because materials and workmanship employed thereon were of the best procurable. For instance, bituminous pavements which appear to be best adapted for this climate have been laid under similar conditions, but have produced dissimilar results, chiefly due to defective materials and more defective construction. Again, wood block pavement, which has been so much condemned in this neighborhood, is one of the best pavements to be seen in most European cities and in Australia, because the blocks used and the methods of construction are entirely different to those in vogue in most American cities.

Brick, concrete, dolarway and the various asphaltic mixtures are the chief pavements upon which the attention of engineers has been concentrated of late. The adoption of the various types for highway construction obviously depends on the varying conditions and circumstances—the location and grades on which they are to be built, and the particular use to which they are likely to be put. A brief reference to each type of pavement may suffice to demonstrate their demerits and merits and their usefulness or otherwise, particularly as applied to main rural highways.

Brick.—The adoption of a brick pavement necessitates the use of an unyielding concrete foundation upon which their stability and durability so greatly depend. The high cost of a concrete foundation, particularly in districts where transportation facilities are not good, and the excessive cost of the bricks, renders this class of pavement heavy in first cost. The objects aimed at in their adoption are the furnishing of a double wearing surface, which will have the minimum of traction resistance and the maximum of wearing resistance. The cheaper ordinary brick, which figured so much in earlier construction, has now been supplanted by the more expensive vitrified brick. The principal advantages of brick pavement are:—

(1) The sure foothold they afford for horses.

(2) Their special adaptability to heavy grades.

(3) The comparatively little dust and mud which they yield.

(4) The ease and expedition with which they can be repaired.

(5) Their durability under moderate traffic.

The principal disadvantages are:—

(1) Their excessive first cost.

(2) The lack of uniformity in the quality of the bricks, some bricks being softer and more porous than others.

(3) The lack of evenness and regularity in the wearing surface.

(4) Their disagreeable noise under team traffic.

Finally, as laid on a rural highway, they appear to be out of all harmony with the remainder of the road and are, therefore, of little or no aesthetic value. However, with the perfecting of a more uniform and properly vitrified brick and the improvement in the modes of construction, there is little doubt that this form of pavement will shortly be more in general adoption on arterial highways.

Concrete.—Until quite recently the use of concrete in the construction of pavements was wholly confined to the foundation, but pavements entirely composed of concrete are now being more generally adopted, not only in city streets but also on rural highways. As in every type of composite pavement, their success depends upon the proper grading of the best procurable materials, and on the workmanship being of the highest order. The advantages claimed for such roadways are:—

(1) The low first cost. It is contended that they cost little more than the bare cost of the foundation used for other composite pavements.

(2) The pavement is a monolith, and therefore the wearing surface cannot separate from the foundation as in other composite pavements.

(3) The surface can be made rough or smooth as desired to meet different conditions.

(4) They require no subsequent coating of material to protect them from the wear and tear of traffic.

(5) They are impervious to injurious oils and gases which affect bituminous pavements in particular.

(6) They strengthen with age.

(7) As they contain no joints, no dirt can collect on the surface and they are therefore easily cleaned.

(8) All the materials are easily procurable.

(9) They are durable under ordinary traffic.

Against these qualifications are set the following disadvantages:—

(1) The noise produced under team traffic.

(2) The cracking and consequent disintegration due to their expansion and contraction under extremes of temperature.

(3) Their injurious effects on horses' hoofs.

(4) The difficulty of maintenance, it being hard to perfectly join up new concrete with old concrete which has been set for some time.

(5) It is not sufficiently resilient and elastic.

(6) Its rigidity is not calculated to withstand the constant blows of horses' hoofs or the heavy impact of motor trucks.

When, however, some of the above drawbacks have been overcome or minimized there is no doubt that concrete roads will be a more marked feature in highway construction in the near future. "Hassam" is a patent form of concrete pavement from which it differs principally in that the rock aggregate of the pavement is laid and rolled instead of being mixed along with the cement, etc., and the cement grout poured into the stone until the voids are filled. When confined to streets with light traffic, where there is no vibrating and impounding action of street cars, etc., it appears to give fairly satisfactory results, but unfortunately it has been laid on business streets of which he subgrade is chiefly composed of "made" ground and therefore has been unable to withstand the heavy compressive, as well as tensile, stresses to which it has consequently been subjected.

Dolarway.—As in other matters, so in pavement. Necessity has been the mother of invention. Dolarway was invented or the idea conceived of applying a thin layer of liquid bitumen to a concrete surface, and sprinkling coarse sand thereon. Such a precaution is alleged to reduce the contraction and expansion common in ordinary types of concrete pavement, by protecting it from the alternating influences of temperature. This so-called wearing surface also reduces the noise, presents a better and more beautiful appearance, saves the horses' hoofs and tends to add to the life of the pavement. The effective results of such treatment are, however, very questionable, the bituminous layer being too thin to afford the necessary elastic, resilient and durable surface, particularly on streets with heavy mixed traffic.

Asphaltic Mixture Pavements.—Under this head are included "bitulithic," "asphaltic concrete" and "sheet asphalt." The latter pavement, not being generally adaptable for rural highways, need not be discussed.

Bitulithic and asphaltic concrete pavements can be laid either on a concrete base or a rock base, the typical bitulithic being chiefly laid on the rock base. The composite parts of the wearing surface of both pavements are very similar, being stone, sand and bitumen. But they are dissimilar in that the sizes of the stone used and the grading of the stone vary greatly. In the case of bitulithic the crushed stone is carefully graded in predetermined proportions, scientifically and mechanically mixed in special paving plants, and the mixture spread on the rock or concrete foundation and carefully rolled to afford a compact wearing and waterproof surface. Asphaltic concrete is similarly prepared with different sizes of crushed stone and similarly applied to the foundation. Although the results produced are not quite alike, the objects aimed at in both classes of pavement are closely akin, and while the typical bitulithic pavements have been in longer use than the generality of asphaltic concrete pavements, the latter are becoming more popular and acceptable because they are unpatented and are, therefore, cheaper in first cost. Now that portable or semi-portable paving plants are in vogue, the use of such pavements has been generally extended to the construction of bituminous concrete roads in rural districts. As such pavements approach nearest to the theoretical and practical conception of a first-class pavement and are particularly adapted to country highways, they are destined to be more adopted than brick, concrete or dolarway pavements. Such bituminous pavements appear to meet the urgent demand for special highway construction, not excessive in first cost, of great durability, and of pleasing appearance, made imperative by the general adoption of automobile and motor truck traffic. As they have met with very favorable results when laid on a rock foundation, an existing macadam road which has proved to be no longer serviceable for the traffic it has to withstand can be readily and easily transformed into a fairly permanent paved highway at comparatively less cost than other types of pavement laid on a concrete foundation. The modus operandi in converting a macadam road into a paved highway chiefly consists in scarifying the existing roadbed, to reduce the crown and afford a bond for laying of additional medium sized rock. The new foundation thus created is consolidated by careful rolling and coated with bituminous paint, upon which is applied usually a 2-inch wearing surface as mixed in the paving plant. Provided always that the materials, mixing and workmanship are all equally good, asphaltic mixture pavements are claimed to be the best adapted for general city work and for use on rural highways. While the perfect pavement to suit all conditions and circumstances has not yet been devised, bituminous pavements approach nearest to the theoretical and practical type of pavement, inasmuch as all the ingredients used therein are natural mineral products, to the grading and mixing of which all the available skill of the laboratory has been applied. Briefly, such pavements possess the following advantages: Durability, resiliency, elasticity, noiselessness and dustlessness. They have a good appearance, are sanitary and can be easily cleaned. In most circumstances they afford good foothold for horses. As regards cost, they are cheaper than most pavements and, taking the cost of maintenance into account, they are cheaper than almost any type of pavement.

The American Society of Municipal Improvements will assemble in Wilmington, Delaware, October 7-10, 1913. The society has for its purpose the dissemination of information concerning municipal departments and municipal works construction and the promotion of improved methods in management.

The question of the disposal of refuse is dealt with in a vigorous and popular way in an illustrated pamphlet, now in course of publication by the Commission of Conservation. The commission is asking the co-operation of the medical health officers in the various towns and cities throughout the country in distributing this pamphlet, and it is hoped the demand for it will be as large as the importance of the subject merits. Pamphlets may be secured gratis by all bodies or persons interested, by applying to the secretary, Commission of Conservation, Ottawa, Ont.

ACTION OF VARIOUS SUBSTANCES ON MORTAR

By Richard K. Meade.

THE following results on the action of various substances on cement mortars were obtained from experiments begun some five or six years ago, and were undertaken to ascertain the action of alkaline waters on concrete, to find out if destructive action really did take place, and also to determine which of these salts ordinarily found in ground water were the cause of such disintegration. The report was published in the form of a paper presented before the convention of the American Society for Testing Materials, at Atlantic City, on June 26th.

The salts usually found in the so-called "alkali waters" of the West are also those which occur in seawater and are those present in largest amounts in many spring and river waters. They are sodium chloride, magnesium sulphate, calcium sulphate, sodium sulphate and sodium carbonate. In order to test the effect of solutions of these substances on cement mortar, a sample of normal Lehigh Valley cement was selected and from it a large number of sand briquettes were made.

Analysis and tests of the cement are given in Table I.

Table I.—Analysis and Tests of the Cement Employed.

ANALYSIS

Silicia, per cent.	20.20
Oxide of iron, per cent.	2.50
Alumina, per cent.	6.96
Lime, per cent.	62.40
Magnesia, per cent.	3.01
Sulphur trioxide per cent.	1.60
Loss on ignition, per cent.	2.38

PHYSICAL TESTS

Soundness

Passing No. 200	77.8 per cent.

Setting Time

Initial set	2 hr., 15 min.
Final set	6 hr., 30 min.

Tensile Strength, lb. per sq. in.

	Neat	Sand
1 day	315	...
7 days	765	245
28 days	875	340
3 months	885	415
6 months	885	435
1 year	890	510

All briquettes were made from a mixture of one part cement and three parts standard Ottawa sand. They were allowed to harden 28 days in air and then immersed in a solution of the salt. The briquettes were piled in such manner that the solution had access to almost their entire surface.

The solutions in all cases except that of the calcium sulphate, which was a saturated solution, were made up of one part of the salt to 100 parts of water, to form practically a 1-per cent. solution. At first the solutions were changed every few days, but after the first month the solutions were changed weekly and after the first year less often. The results obtained are given in Table II.

First it should be remembered that the 28-day strength of briquettes kept in air is much less than that of those kept in water. As will be seen from the results given in Table II., the sulphates have a marked action on concrete, which seems to be most apparent in the case of the magnesium salt. The action of magnesium sulphate on cement mortars has been discussed quite voluminously of late and I will not go into it to any length in this paper beyond stating that we carefully analyzed the affected portion and the unaffected portion of a sand briquette which had been stored in a solution of magnesium sulphate. These analyses are given in Table III.

Table II.—Action of Various Salts on Cement Mortars.

	— Tensile Strength, lb. per sq. in., after immersion in —					
Age in Soution	Magnesium Sulphate	Magnesium Chloride	Calcium Sulphate	Sodium Sulphate	Sodium Chloride	Sodium Carbunate
0 days†	219	219	219	219	219	219
7 days	268	245	227	257	236	225
28 days	272	300	300	334	268	277
3 months	287	315	334	354	299	324
6 months	196	202	314	378	287	320
1 year	*..	115	209	271	310	337
2 years	...	*..	*...	141	325	360

* Disintegrated.

† The briquettes were aged 28 days in air before immersion.

Table III.

	Before Immersion	Unaffected Portion	Affected Portion
Silica, per cent.	75.12	73.96	60.40
Oxide of iron, per cent.	0.52	0.60	0.30
Alumina, per cent.	1.15	1.30	0.64
Lime, per cent.	14.80	14.50	14.21
Magnesia, per cent.	0.70	1.66	3.64
Sulphur trioxide, per cent.	0.33	0.83	5.78
Loss on ignition, per cent.	7.02	7.14	14.97

The large increase in the magnesia and sulphur trioxide and the decrease on the oxides of iron and alumina indicate the elements which react with each other. The loss in silica may be due to chemical action also, but as the surface of the briquettes was very much attacked and the sand grains could be scraped away with the finger, I am inclined to think that the lower silica in the disintegrated portion was probably due to mechanical causes rather than chemical action. It will be noted that in almost all cases the first effect of the solution was to increase the strength of the briquettes and that signs of disintegration in no cases became evident until after a period of three months in the solution.

Some of the briquettes were even boiled in a 5-per cent. solution of magnesium sulphate for several days, and in all cases the briquettes were much stronger after boiling than they were before and fully as strong as briquettes boiled in pure water, showing how slow the action of the sulphates is.

The briquettes which failed were considerably swollen and presented much the appearance of a baked potato which has burst its jacket.

Various authorities have proposed at different times the use of divers ingredients in concrete exposed to seawater, with a view to their reacting with the salts of the latter to form insoluble compounds which would protect the concrete. Most persistently suggested of these are the salts of barium, which form with soluble sulphates insoluble barium sulphate. I tried both barium chloride and barium carbonate. These were ground very finely and mixed with the cement. I employed 2 per cent. of barium chloride with the cement, and also 2 per cent. and 5 per cent. of barium carbonate. Sand briquettes were made from these mixtures and the test pieces stored in a magnesium sulphate solution containing 10 grams of the salt to the liter. The results are given in Table IV., and, as will be seen, none of these compounds arrest the destruction.

Table IV.—Action of Magnesium Sulphate on Cement Mortars Containing Barium Compounds.

* The briquettes were aged 14 days in air before immersion.

Some years ago an English chemist suggested the use of finely ground, burnt red brick as an admixture for concrete which was to be used in sea-water. After reading this paper it occurred to me that the resistance to sea-water claimed for high-iron cements might be due to the presence of oxide of iron in the cement. I therefore had sand briquettes made up containing oxide of iron in various forms and conditions, namely, red or ferric oxide, magnetic oxide of iron, venetian red (an impure oxide of iron made from low grade iron ores, so-called "paint ores" of the Lehigh district), and finely ground red brick, using of these 5 per cent. of the weight of the cement in each case and placing the briquettes in a 1-per cent. solution of the magnesium sulphate. The results are given in Table V. As will be seen, the additions of iron compounds are in no way beneficial to cements to be employed in sea-water.

Table V.—Action of Magnesium Sulphate on Cement Mortars Containing Iron Oxides, Etc.

1 year	125	105	Disintegrated	Disintegrated

* The briquettes were aged 14 days in air before immersion.

I next tried waterproofing the mortar on the theory that if the circulation of water through the pores of the mortar could be stopped no chemical action could take place. I employed for this purpose both a high-calcium and a magnesium-hydrated lime, road oil (as recommended by Page), a mixture of silicate of soda solution and fish oil (a well-known waterproofing compound), and lime soap (the basis of many waterproofing compounds). I also tried dipping the briquettes first in a hot solution of soap and then in one of alum (Sylvester's Process). The results of the tests of sand briquettes made from these mixtures and stored in magnesium sulphate solution (10 grams to the liter) are given in Table VI.

Table VI.—Action of Magnesium Sulphate Solution on So-Called Waterproofed Mortars.

Age in 1 per cent. Solution of Magnesium Sulphate	Tensile Strength, lb. per sq. in., of briquettes containing— 15 per cent. of Hydrated Lime (Calcium)	15 per cent. of Hydrated Lime (Magnesian)	10 per cent. of Road Oil	2 per cent. of Lime Soap	2 per cent. of of Oil Silicate Soda	Treated with Alum and Soap
0 days*	215	215	165	185	160	220
7 days	215	225	200	210	200	235
8 days	315	320	210	250	245	275
23 months	245	260	260	275	260	265
6 months	200	245	210	230	225	215
1 year	120	105	140	180	165	185

* The briquettes were aged 14 days in air before immersion.

It will be noted that, while the disintegration is evidently taking place in these test pieces, all of these compounds seem to arrest it to some extent at any rate, and in the case of the lime soap and Sylvester Process this is quite marked.

I also investigated the action of magnesium-sulphate solution on cements high in silica. For this purpose samples of commercial cement, one high in silica and low in alumina and one low in silica and high in alumina, were selected; sand briquettes were made of these and immersed in a solution of magnesium sulphate containing 20 grams to the liter, or practically a 2-per cent. solution. The cements selected had the following analysis:—

	Low-Alumina Cement	High-Alumina Cement
Silica, per cent.	23.24	19.86
Iron Oxide, per cent.	2.25	2.56
Alumina, per cent.	5.03	7.60
Lime, per cent.	63.55	63.12
Magnesia, per cent.	3.05	3.10
Sulphur trioxide, per cent.	1.51	1.66

As will be seen from Table VII., the low-alumina cement resists the action of magnesium sulphate much better than the high-alumina one.

Table VII.—Action of Magnesium Sulphate Solution on High and Low-Alumina Cements.

Age in 2 per cent. Solution of Magnesium Sulphate	Tensile Strength lb. per sq. in., of— High-Alumina Cement	Low-Alumina Cement
0 days*	242	225
7 days	318	307
28 days	404	430
3 months	402	476
6 months	230	472
1 year	Disintegrated	500
2 years	...	425

* The briquettes were aged 14 days in air before immersion.

In the above experiments, both cements were commercial cements; but the high-alumina cement when received was not quite so finely ground as the other one, so it was ground to practically the same degree of fineness in a small jar mill (or to 86.2 per cent. passing the No. 200 sieve), so that the fineness of the two samples might in no way influence the results. Both these sements were made from cement rock and limestone.

In connection with the use of concrete for mine props, where it is often exposed to the action of dilute solutions of sulphuric acid, the following experiment was tried. Sand briquettes were allowed to harden 28 days and then were placed in a solution containing 250 grains of sulphuric acid (H_2SO_4) to the gallon. The solution was changed frequently and the briquettes broken at regular intervals. The disintegration of concrete by such acid water is shown by the following:—

Age in Solution	0 days	7 days	28 days	3 mos.	6 mos.	1 year
Tensile Strength, lb.	226	299	300	280	176	Disintegrated

Several years ago the question of the action of oil on concrete was brought up at one of the meetings of this society in connection with a paper by Professor Carpenter. In his experiments, oil was mixed with the concrete. In the discussion which followed the reading of the paper, a number of gentlemen suggested that what was needed most was information relative to the action of oil on concrete which had already hardened, in view of the employment of concrete for machinery bearings, engine room and factory floors, etc., where it is subjected after being fully hardened to the oil which leaks from the bearings of the machinery. I went home from this meeting and had a number of sand briquettes made and allowed them to harden two weeks in air. These were stored in air, in engine oil, in cylinder oil, and in black oil, and broken at stated periods. The results are given in Table VIII.

It will be noted that the engine oil and the cylinder oil have practically no effect upon concrete. One would think that as the latter has a considerable proportion of

animal oil in its composition it would be apt to appreciably affect concrete exposed to it. On the other hand, the action of the black oil seems strange in view of the

Table VIII.—Action of Lubricating Oils on Concrete.

fact that it is a straight mineral product. All of these briquettes had absorbed considerable oil, the actual gain in weight of each set at the end of the year being as follows:—

In engine oil ..... 10.6 per cent.
In cylinder oil..... 10.0 per cent.
In black oil ..... 12.0 per cent.

The briquettes in the black oil had not swollen perceptibly and seemed merely to be weak.

The experiments given above were all made upon very small test pieces and hence the action of the solutions upon them were much more rapid than they would be upon a large mass of concrete.

The paper was followed by lengthy discussion, Dr. Allerton S. Cushman, of the Institute on Industrial Research, Washington, stating that his experiments largely corroborated those of Mr. Meade. As a probable cause for the disintegration of concrete in alkali waters, discussion tending to show that chemical changes cause undue expansion, and that the best protective methods of preserving concrete where used in localities having black alkali waters, as is the case in many parts of the west, were by the use of coal tar oil. Experiments have also shown that briquettes tempered with copperas have never shown signs of rupture nor have they cracked when submerged in alkali water, and that after having been submerged in this water, they get very hard. Others have shown that concrete in waters carrying sulphates almost invariably change the calcium hydroxide to calcium sulphate, and that this chemical change, demanding more room for increased expansion, disrupts the concrete, and in but a comparatively short time causes disintegration. Tests also showed that in using black oils for waterproofing, trouble might be caused and disintegration follow if the oil used contained even a trace of sulphuric acid. The author of the paper stated that the oil used in the tests as referred to in his paper was a residual oil as used only for the lubrication of very heavy machinery, and that the very slight flaking or sloughing off was on the surface of the foundation only, and did not continue into the concrete, although considerable oil was absorbed by these foundations.

Reference was made then to a method of waterproofing cement used in construction in sea-water. This method is credited to Arthur Rea, of France, and consists of adding a small percentage of gypsum, say, 5 to 20 per cent., to accelerate action, and to add to the concrete finely crushed marble. So far as is known, this method has proven very satisfactory in that country, although experiments made along these lines in Boston harbor, using six representative brands of cement, showed various results with these different cements. At the end of six months all briquettes tested had been slightly reduced with the exception of those made of one brand of cement. In adding waterproofing materials, it was stated in this discussion that the action of a solution of some salts, if added while plastic, will cause the concrete to expand unusually, while one or two others may show no such effect, but when added after the concrete has set, some of these solutions may cause the concrete to disintegrate. Many cases are in existence where concrete in sea-water along the Atlantic coast shows clean sharp edges after having been subject to this water for five years.

AMOUNT OF CEMENT FOR CONCRETE.

Mr. Stanley Macomber, city engineer of Centralia, Wash., in an article in the the Iowa "Engineer," states that a number of engineers in Washington are using clauses similar to the following in connection with their specifications for concrete work:—

Every cubic yard of concrete 1:3:6 mixture shall contain at least 4 sacks of cement.

Every cubic yard of concrete 1:3:5 mixture shall contain at least 4½ sacks of cement.

Every cubic yard of concrete 1:1:1 mixture shall contain at least 12 sacks of cement.

Every 2 cu. ft. of top mixture 1:2 shall contain at least 1 sack of cement.

For cement over this amount nothing will be paid the contractor.

For every sack of cement under the above amount the regular price shall be deducted from the total sum due to the contractor.

The contractor to figure on the above amounts rather than on the direct mixture.

Arrangements must be made with the city engineer for the proper inspection of the amount of cement used.

It is also stated that during the day the inspector tries to keep the mix as near correct as possible, and at night the empty cement sacks are counted and a material slip filled out, signed by the inspector and the contractor. A copy is given the contractor and a copy put on the file in the office. When it comes to final settlement these slips are taken as receipts for the amount of cement used. The amount of cement hauled on to a job is also kept in this manner as a check.

The area and mileage of street paving of various classes in the city of Philadelphia is given as follows in the annual report of the Bureau of Highways, of which Wm. H. Connell is chief:—

Character.	Sq. yards.	Miles.
Granite block	6,653,532	352.99
Asphalt (sheet)	6,959,656	472.35
Asphalt (block)	72,532	7.49
Vitrified brick	2,376,224	163.63
Cobble	162,775	14.02
Rubble	93,182	6.69
Slag block	78,071	8.13
Cement and granolithic	54,242	11.03
Wood block	121,505	4.06
Totals	16,571,719	1,040.39
Bituminous macadam roads	312,104	29.01
Waterbound macadam roads	3,035,429	261.31
Total macadam roads	3,347,533	290.32
Grand total (improved pavements and macadam roads)	19,919,252	1,330.71

THE DESIGN OF CENTRAL HEATING SYSTEMS

PART II

THE PRODUCTION OF HEAT THE OBJECTIVE TO BE KEPT IN MIND—TYPES OF MACHINERY—TUNNELS, PIPING SYSTEMS, AND OTHER ACCESSORIES.

By A. G. CHRISTIE, M.E.,
Assistant Professor of Steam Engineering, University of Wisconsin.

The Design of the Heating Station.—The central heating plant should be so designed that the production of heat is its prime objective. The heat, however, may be developed with high pressure on the boilers, and this pressure may be reduced by passing a portion or all of the steam through engines. A portion of the heat is thus converted into work, and may be utilized to drive electric generators. Any further heat demand may be met by passing high-pressure steam through a suitable reducing

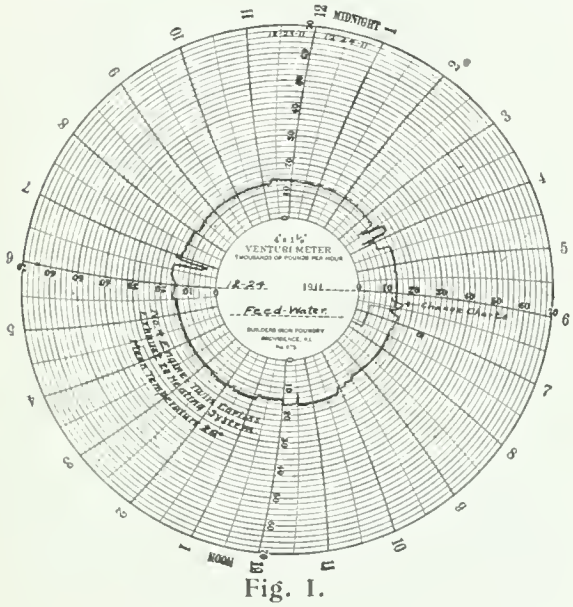

Fig. 1.

valve. In other words, the station should be so designed that heat is the main output and electricity a by-product. This condition is secured when the demand for steam by the engines driving the generators is entirely submerged by the average demand for heat during a greater portion of the heating season. It is possible with this arrangement to select boilers of capacity proportional to the heating loads, and to keep in service the proper number of boilers to most economically meet the demands for heat, which will vary almost directly with the outside temperature. There are, then, no extreme peak loads during the day in the boiler-room, and consequently no fires are kept banked between peaks.

Fig. 1 shows a typical chart from the Venturi meter on the boiler feed-line of the Capitol Heating Plant at Madison, Wis., where the steam demanded by the power load shown on Fig. 2 is entirely submerged by the heating load, which, as the chart shows, is uniform for the twenty-four hours.

When a plant is run primarily for generating electricity and the exhaust steam is a by-product and required to the amount represented by the average load on the plant, there will be peak loads at certain times of the day, and at such times exhaust steam will be wasted. Boilers must be kept with banked fires to meet these peak demands for steam, and, on account of these stand-by losses, operation must necessarily be less efficient than when the steam demand for heat predominates, and, owing to the nature of the service, is practically uniform.

Many of the older heating systems were installed with the idea of using exhaust steam as a by-product and with no real value. In consequence, they have been financial failures on account of inefficient plant operation. In some other cases the overhead plant charges were not equitably distributed between the electric services and the heating system, resulting in ridiculously low heating rates.

Several utilities which supply cities with hydro-electric power find it necessary to maintain auxiliary steam plants in the city, especially when the power has to be transmitted for some distance from its point of generation. Frequently fires are banked under the boilers of these auxiliary plants at all times for either emergency or peak-load service. Under such conditions a heating system should prove a valuable addition to such service, not only from an operating, but also from a financial standpoint.

It can thus be seen that there is considerable justification for the assertion that the heating plant must be primarily for heat and not for power. This fact is now recognized by all leading heat engineers, as instanced by an abstract from a recent address of Mr. C. R. Bishop, in which he states: "To secure maximum results, the demand for steam for heating should be slightly in excess of the *maximum amount* of exhaust steam available at all times."

The detail design of every central station presents a new set of problems, so that no specific rules of design can be laid down. The size of the plant is dependent on the extent of the proposed service. The character of the units to be installed is determined by the fuel cost at the plant. If coal is cheap, it would not be profitable to install expensive equipment. But where coal is dear, consideration should then be given to the most efficient equipment that is on the market, and additional special apparatus may be installed to secure economical operation. It is, therefore, advisable to determine as closely as possible the probable future cost of coal before the designs are made, and to be guided thereby in the selection of equipment. When purchasing engine equipment for a central station, those types or combination of types should be selected which will serve throughout the whole year, and will, therefore, not involve overhead charges with no returns during the summer season.

The plan of the station should always provide for future extensions when such are contemplated. A usual arrangement is to place the engine and boiler-rooms side by side, and with the backs of the boilers towards the brick wall separating the two rooms. The engines may be placed on a higher level than the boilers, and the basement below the engine-room will serve as a pump

and heater room, and also as a distributing centre for the heating system.

When a heating station is located in a district where real estate is extremely high, it may be desirable to make the plant double-decked, i.e., the engines are placed on a second floor directly above the boiler-room. This construction is feasible when steam turbines are used. However, when these engines are run condensing, this arrangement is not desirable, as it is not economical to raise water for cooling purposes to such a height. This objection does not hold when the units generally operate non-condensing.

A large storage of coal, either in bunkers or exterior to the power plant, is absolutely essential to guarantee a supply of heat in case of such emergencies as strikes on the railroads or in the mines, or freight blockades cutting off the coal supply. Except at the lake ports, all Wisconsin's coal supply comes from Illinois, and is hence subject to blockades and snow troubles. When land is dear, coal bunkers for storage should be built in the plant itself, in which case coal-conveying machinery must of necessity be installed. In other cases, the size of the plant and the cost of labor will be factors in deciding the advisability of installing coal and ash-handling systems. Regarding the disposal of ashes, many utilities have found that building contractors and others will remove all well-burned ash and clinker for use in concrete construction and for filling in.

When the plant contains only a few boilers of small size, hand-fired furnaces will give the best economy, provided these furnaces are properly designed and are handled intelligently. Furnaces of the Dutch oven type or with overhead brick arches should have a preference, as they aid materially in reducing the smoke nuisance.

The cost of labor is paramount when considering the question of hand-fired furnaces or mechanical stokers. In general, one fireman can attend to coal, water and ashes on 300 horse-power of boilers in a hand-fired plant. With automatic stokers, overhead bunkers and down-spouts, one fireman can easily take care of 2,000 horse-power, or even 3,000 horse-power, depending on the size of the boilers, and at the same time maintain a high and uniform degree of efficiency. It will generally be found economical to install stokers where three or more boilers of 300 horse-power or over are continuously in service, especially when screenings or slack are burned.

By abstracting part of the waste heat from the flue gases from the boilers economizers aid in the further recovery of the heat generated in the furnace. Such apparatus is sometimes desirable where coal is expensive. The scale-forming properties of the water used in the economizer will determine to a large extent the expense involved in cleaning. In hot water systems the water is frequently circulated through an economizer before being pumped back into the system. By cooling down the flue gases, the draft on the boilers is reduced by economizers when chimney draft only is used. Hence, a higher and more expensive chimney or a mechanical draft apparatus must be employed. Some engineers prefer to install more heating surface in their boilers than to use economizers. At best, economizers are expensive and require considerable care to be kept in good working order.

The piping system of a heating station cannot be specified by any set of general rules. However, all such piping should be in simple systems, and valves should be easily accessible at all times. Engineers should insist on high-grade pipework throughout the plant.

It is always advisable in plants of sufficient size to warrant the expense to install Venturi meters on the boiler feed-line of a steam plant or on the delivery line of a hot water plant. This enables reliable records to be kept of the heat output of the plant and provides a means for checking the efficiency of the heating system.

The selection of prime movers for generating electricity will be influenced by the nature of the electrical service, the amount of the heat demand and the first cost of equipment. If it is desired to keep the electrical load submerged in the heating load at all times, and if the demand for steam for such service is almost equal to that of the heating system, then it will pay to put in the most economical engines obtainable in order to get the best results from the steam available. High-priced single or compound engines of the Corliss or four-valve type would be installed. If vertical compound engines of the high-speed English types were available, these would deserve consideration, both with respect to low first cost and high efficiency. In some plants compound condensing engines are installed which can run

Fig. 2.

during the heating season either as simple engines, or a quantity of steam can be withdrawn from the receiver for heating. During the summer season such engines are run condensing. However, in view of recent developments in low-pressure steam turbines, it would seem more advisable and less expensive to install such units to utilize the excess exhaust steam over heating requirements during peak loads on warm winter days and in summer.

Many improvements have been made on non-condensing steam turbines in recent years, so that these should be given careful consideration in selecting plant equipment. Bleeder types of turbines, which provide for the extraction of a portion or all of the steam after it has passed through the first stage, have become standard for heating purposes and are now being installed quite generally instead of steam engines. Steam turbines are adapted to the design of heating stations on account of their low first cost, small weight and cheap foundations. As there is no internal lubrication, oil troubles are avoided in the exhaust heating systems.

A 750 K.W. 60-cycle non-condensing steam turbine operating at 150 pounds pressure and 5 pounds back pressure above atmosphere will have a steam consumption of about 40 pounds per K.W.H. A 1,000 K.W. 60-cycle machine will have about 1 pound per K.W. better water rate at full load. On both of these machines the steam consumption at half load will be about 2 pounds per K.W.H. higher than at full load. A standard 750 K.W. condensing turbine will have a steam consumption at full load of about 19.5 pounds per K.W.H., and at half load of about 22.5 pounds. The 100 K.W. condensing turbine would have a steam consumption of about 19.0 pounds per K.W.H. at full load and 21.0 pounds at half load.

If these condensing turbines are provided with automatic bleeding devices to take steam for the heating system at 5 pounds pressure above atmosphere, it will be possible with 150 pounds steam pressure and 28 inches vacuum to extract a maximum of 15,000 pounds of steam per hour from the 750 K.W. turbine at half load, with a total flow of steam at the throttle of about 16,000 pounds. At full load the maximum extraction would be

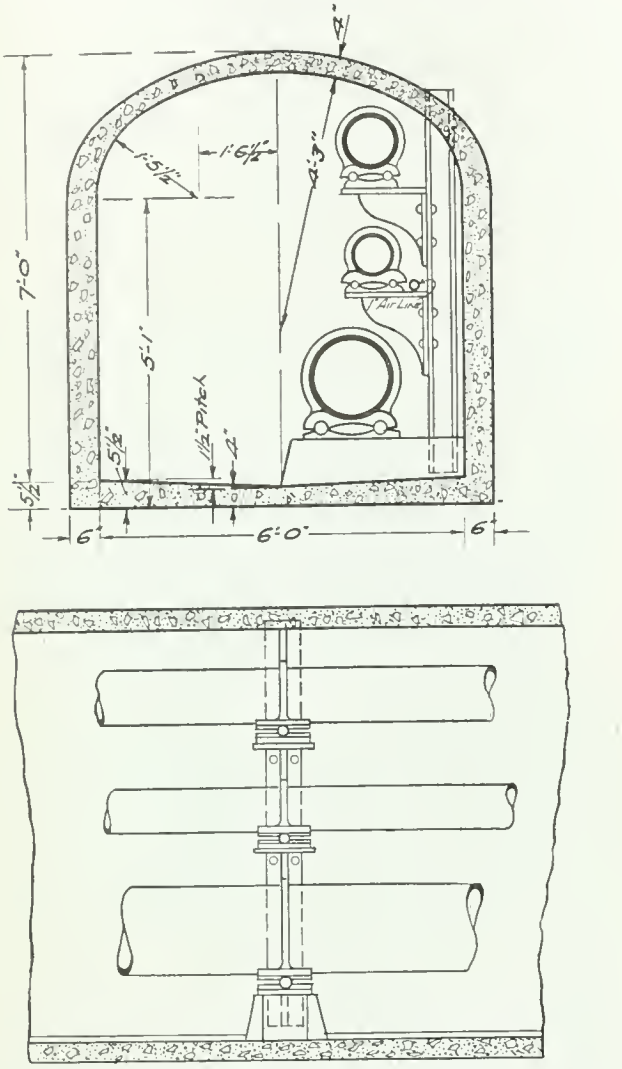

Fig. 3.—University of Wisconsin—Standard Heating Tunnel.

about 28,000 pounds with a total flow at the throttle of about 29,000 pounds. The 1,000 K.W. condensing turbine under similar conditions will have a maximum bleeding capacity of about 19,000 pounds per hour at half load, with a total flow at the throttle of 20,000 pounds. At full load it is possible to withdraw 37,000 pounds per hour with a total flow at the throttle of 38,000 pounds.

This data, from a leading manufacturer, is presented to show the results that can be expected from such type of turbine. The advantage of the bleeder type lies in the fact that it may be operated condensing entirely during the summer months, and thus high efficiency may be maintained.

There has been considerable information published relative to the bleeder type of turbine. Further data on this question can be found in a paper by A. H. Kreusi on "Heating in Connection with Steam Turbines," read before the National District Heating Association at Detroit in June, 1912, and also a paper by E. D. Dreyfus on "Notes on an Economic Survey of Combined Central Heating and Electric Plants," presented at the same meeting. The latter paper presents some interesting graphical diagrams showing the results obtained with Westinghouse bleeder turbines.

In many plants it has been found more desirable to install separate condensing units than to attempt to adapt one type of engines to all conditions of operation. These condensing units can be used on the peak loads. Occasionally storage batteries are also provided to improve the load factor by helping out on peaks.

The boiler feed-pumps in a large central station should be of the turbine driven type, although in small plants duplex steam pumps with automatic governors are generally used.

The circulating pumps in hot water heating systems are now generally of the centrifugal type, driven by non-condensing steam turbines, which exhaust into the heaters. Sometimes these pumps are motor driven, though this is not common.

Pipe Lines and Conduits.—The most important portion of the district heating equipment is the underground transmission system. For economy in operation this should be made of the very best possible construction, and should be easily accessible for repairs at all times. On the other hand, too high first cost results in high fixed charges on the service rendered. The conduits, pipe lines and auxiliary service must be designed so as to provide the most economical system in operation that can be installed with the capital available.

The franchise or permit of the heating company allows it to make use of the streets and alleys of the city. The plan of the city will show at a glance whether it is possible to use the alleys for conduits. The choice between streets and alleys depends on two things: (1) The relative cost of street and alley construction; and (2) the location of the buildings to be served relative to the streets or alleys. It has been authoritatively stated that, other things being equal, alley construction will cost 15 to 30 per cent. more for labor than street work, owing to the difficulty of working in the narrow space. An important factor affecting street construction costs is the amount of paving that has to be torn up and relaid. The heating companies are obliged in most cities to bring their service pipes to the curb line in a street and to the property line in an alley. This item of expense should not be overlooked in choosing between street and alley construction, for on wide streets the extra cost for service lines will more than eat up the saving in labor effected by street construction.

The form of conduit to be employed in any given installation will be dependent on local considerations. When a large main or a number of pipes, such as high-pressure steam, low-pressure steam, condensation return or other piping must be laid for some distance in one direction before branching off for distribution, it is probable that a reinforced concrete tunnel would be most satisfactory. However, it will generally be found that the greater portion of all heating systems are laid in some form of underground conduit.

Piping tunnels allow joints to be watched and repairs and alterations to be made with comparative ease. Their first cost is high, but they never need opening up if properly built. Fig. 3 shows a section of standard piping tunnel used at the University of Wisconsin. The pipes are carried by saddles with ball bearings resting on brackets fastened to vertical I-beams, which are imbedded in the concrete. Any section of pipe can be readily removed with this construction. Anchors and expansion joints are provided at proper intervals. Tunnels need

to be well underdrained, and should be provided with air-tight manholes at proper intervals. The radiation losses from piping in tunnels can be reduced to comparatively small amounts if covered to a sufficient depth with first-class moulded insulation materials.

If the distribution mains are too large for the service connected up, the per cent. loss will be unreasonably large, while if the capacity is increased to its ultimate limit, the line losses will become a very small percentage of the heat transmitted. Thus a line designed for 200,000 square feet of radiation will show a line loss of 10 to 20% of the heat supplied when only 50% of the service is connected. But when the whole ultimate load is applied the loss would become only about 4%. The normal condensation from radiation should then not exceed 0.05 pound per square foot per hour.

The requisites for good construction and efficient operation of pipe conduits are as follows:—

1. Drainage must be provided to remove all water accumulations from possible contact with pipe lines.
2. There must be adequate provision for expansion.
3. Drips and traps must be provided at intervals to remove condensation from radiation.
4. The pipe insulation must be efficient.
5. The conduit itself must be of good mechanical construction.

Drainage must be provided to keep both conduit and insulating materials dry at all times. This drainage is usually secured by first laying a tile drain in the bottom of the trench. Then a layer of coarse crushed stone is laid above and around this tile. The conduit can now be placed so that there is a filling of crushed stone on either side of it as high as its top. This enables the water percolating through the soil above to find an easier path to the drain than through the conduit itself.

Expansion joints must be provided at frequent intervals along the mains to take up the expansion and contraction from changes in temperature. A form of expansion joint which can be packed under pressure is shown in Fig. 4. This was designed by Mr. J. C. White, and has been in use for several years with entire satisfaction on both the Wisconsin State Capitol heating system and the University of Wisconsin heating system. The main body of this expansion joint is of cast-iron, and is bored out for the stuffing-box and threaded to receive the retainer ring as shown. The telescoping or slip section of pipe is made of tobin bronze, turned up and polished on the outside. The four packing rings, marked "a," and the two clamp rings, "b," are also of tobin bronze, and are all split in a similar manner to piston rings. The bull ring "c" has four holes at right angles to each other which connect the inside annular space with the outer annular ring, which in turn connects to the ¾-inch blow-off pipe on the lower side of the cast-iron body. The retainer ring "d" is of cast-iron, and is screwed in place by a special socket wrench. The packing may be of any "soft" variety, and can be withdrawn at will with steam on the line by simply opening the blow-off valve to the atmosphere. It is surprising how little steam leaks past the packing-rings even when the blow-off valve is open. This joint has been equally as satisfactory on high-pressure lines as on low-pressure. This form of expansion joint has proven the most satisfactory of any using soft packing. Goose-neck bends have been used occasionally, but are not suitable for conduit work.

There are several forms of expansion joints giving satisfactory service on low-pressure lines, and which employ copper diaphragms to take up the expansion and contraction of the piping. They are placed usually about 100 feet apart, with anchors midway between. A service outlet to customers is generally provided at the top of the cast-iron body of these expansion devices, and also at the anchor, fitting so that dry steam only passes out of the main.

Manholes must be provided above these joints, and also above any valves or other equipment that may need adjustment or inspection. However, manholes are a source of great heat loss, and hence as few should be used as is consistent with efficient operation of the lines.

The radiation loss from piping is dependent largely on the character of its insulation, the depth underground that the piping is placed, and, as already pointed out, the dryness of the conduit and its insulating material. Some insulating materials deteriorate with age. Gifford, in his book on "Central Station Heating," gives the following formula for finding this radiation loss:—

$$H = A \times C$$

where H = pounds of steam condensed by radiation, A = square feet of outside surface of piping, fittings, service connections, expansion joints, etc., in the heating mains, and C = a constant for each class of covering as shown in the following table:—

Table 3.—Coefficients for Radiation Losses.

*Values of C are given in pounds of steam. Multiply these values by 1;000 to get the approximate heat units.

It is very difficult to obtain any figures of actual tests or other records showing line losses in actual plants.

Mr. C. R. Bishop, of the American District Steam Company, states that with their standard wood-log construction the transmission loss of a low pressure steam system averages about 0.044 pounds of steam per hour per square foot of surface of underground mains, to which must be added a small percentage to equal unaccounted-for steam due to meter inaccuracies, leaky air vents, etc. Gifford, in his book on "Central Station Heating," states that the radiation loss in a steam system equals 0.05 pounds of steam per hour per square foot of underground main. The superintendent of one of the largest heating systems in Illinois, in a personal communication, stated that the loss in their mains is equal to 6% of the total steam leaving the station. This system includes 1,800 feet of 18-inch main installed in a brick tunnel and covered with a 2-inch covering of asbestos sponge felt, the remainder of the system has wood-log conduits.

The materials used for insulation will be discussed later in connection with conduit construction.

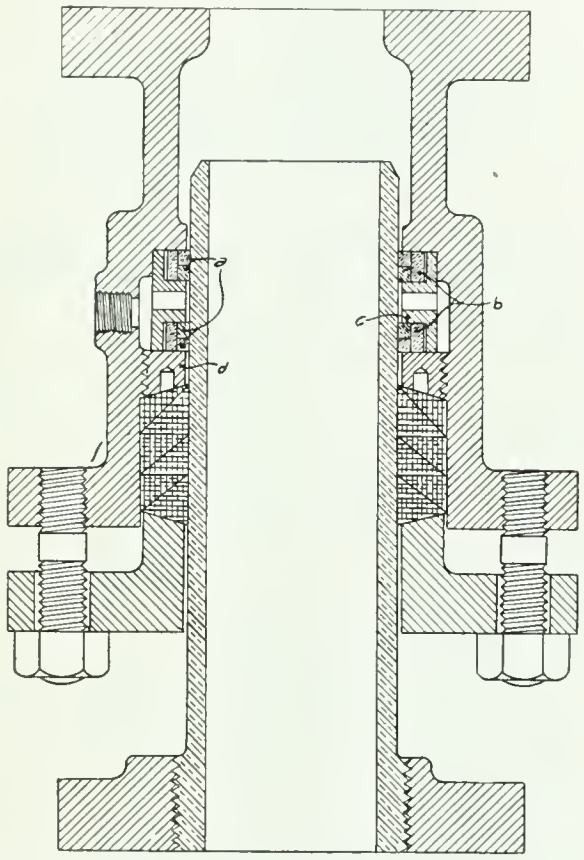

Fig. 4.—White's Expansion Joint.

The question of materials for pipe lines is naturally one of considerable importance. The American District Steam Company, who have probably had more experience with heating systems than any other concern in this country, have always maintained that strictly wrought iron pipe with long recessed couplings was far more durable than steel pipe. However, recent tests on steel pipe tend to show that there is not so much difference between the two classes of pipe as is claimed. Besides, it has become almost impossible to procure strictly wrought iron pipe except at prohibitive prices.

The proper size of the pipe lines to be installed is determined by their ultimate capacity and by the allowable drop on the lines. This will be determined with exhaust steam by the back pressure which can economically be permitted on the engine or turbine. With hot water, the designer must select such a pipe size that the sum of the losses in pumping due to friction, and in radiation, is a minimum. These calculations must be based in each case on the ultimate capacity of the pipe line.

The friction losses in heating mains must be carefully calculated before the final sizes are selected. A compromise has usually to be effected between the piping system with the least friction drop and that with the least heat losses. In general, however, the system must be so designed that a pressure of at least one pound above atmosphere must be maintained at the radiators at the extreme end of the system without requiring at the station too high a back pressure in the case of low pressure steam or too high a head to pump against in the case of hot water.

The allowable pressure drop depends largely on the pressure that is to be maintained at the station end of the system. For instance, the friction loss with 10 pounds pressure could be about double that of a system with 5 pounds pressure at the plant. There is a considerable mass of data on hand for calculating the sizes of steam mains for known pressure drops, but much of this is of a conflicting nature. For instance, Mr. C. R. Bishop states that in designing large low pressure steam systems with a maximum initial pressure of 5 pounds above atmosphere, the friction loss should not exceed one-quarter pound per square inch per 1,000 lineal feet of main. Gifford, in "Central Station Heating," gives sets of curves for allowable pressure drops for both hot water and steam. Values taken from these curves are very much in excess of those quoted by Bishop, and it would seem, therefore, that they are not very applicable to large heating systems.

Professor H. V. Carpenter gives a series of curves for the flow of steam through pipes in Power, December 17, 1912, but these curves are principally applicable to high pressure mains, as the lowest pressure drops plotted are one pound per square inch per 1,000 lineal feet of main. These diagrams, however, could be easily replotted for use on low pressure steam work. They are based on the formula of Unwin, which was confirmed later by tests made by Professor R. C. Carpenter and G. H. Babcock, and are probably correct enough for ordinary conditions.

$$W = 87.5 \sqrt{\frac{PYd^5}{L\left(1 + \frac{3.6}{d}\right)}}$$

$$\text{or } P = 0.0001306 \frac{W^2 L\left(1 + \frac{3.6}{d}\right)}{Y d^5}$$

where W = weight of steam delivered in pounds per minute
P = drop in pressure in length L
L = lineal feet of pipe
d = diameter of pipe in inches
Y = mean density of the steam in the length of pipe under consideration in pounds per cubic foot.

Mr. Konrad Meier, in his book "Mechanics of Heating and Ventilating," reviews the various formulas proposed for the loss in pressure from friction on the flow of steam through pipes, and deduced the following formula for low pressure steam:—

$$P_f = 0.0257\ Y \frac{v^{1.97}}{d^{1.18}}$$

where P_f = pressure drop per foot of pipe
Y = mean density of the steam
v = velocity of the steam in feet per second
d = diameter of pipe in inches.

These exponents apply to steam at pressures slightly above atmosphere. The author also presents charts for use in solving these equations, but the values apply more directly to isolated plant construction than to central station mains.

The friction loss in hot water mains can be approximated closely by applying the well-known formula of hydraulics

$$h_f = \frac{a\,L}{D} \cdot \frac{v^2}{2\,g}$$

where h_f = feet of head lost in friction, a = friction factor which, for wrought iron or steel piping, may be taken as equal to 0.02, L = length of pipe in feet, D = diameter of the pipe in feet, and $2g = 64.4$. This formula may be applied when all the water entering one end of the pipe passes out at the other. When the water is all taken off at intermediate tappings and the velocity at the extreme end is zero, the loss will be about one-third of this amount. For hot water systems in service the actual conditions lie somewhere between these extremes and so the actual loss must be assumed in the proportion to the amount drawn off. Hoffman, in his "Handbook for Heating and Ventilating Engineers," suggests using two-thirds of the value of h_f for hot water service mains with the usual customer's connections.

(To be continued.)

WATER WASTE PREVENTION IN NEW YORK CITY.

By I. M. De Varona,
Chief Engineer, Department of Water Supply, Gas and Electricity, New York City.

TO avert the threatening danger of a serious shortage of supply for Manhattan and The Bronx in 1912, and, later, to avoid, if possible, the large expense attending the development of additional sources of supply for Brooklyn, which would otherwise have been required to adequately provide for the consumption in that borough until the Catskill water was available, the Department of Water Supply, Gas and Electricity of New York City instituted a vigorous campaign to reduce waste. This undertaking forms the basis of a paper read by Mr. I. M. De Varona at the recent American Waterworks Association convention at Minneapolis, of which paper this article forms a part. The intended purpose was fully and most satisfactorily accomplished in both the above-mentioned cases. The crisis of 1912, in Manhattan and The Bronx, was tided over, and Brooklyn may now safely await the introduction of the Catskill supply without further developing its watershed.

The estimated daily reduction in consumption in Manhattan and The Bronx reached a maximum of 71 million gallons in August, 1911, averaged 65 million gallons for the last 6 months of 1911 and almost 50 million gallons for the year 1912, while the total reduction since the beginning of the work in the fall of 1910 to April 1, 1913, aggregated over 39,700 million gallons. In Brooklyn the maximum reduction of 34 million gallons daily was effected in February, 1913, and the average daily reduction since August, 1912, the commencement of the house-to-house inspection, to April 1, 1913, amounted to 25 million gallons, while the total saving since the beginning of the pitometer work in July, 1910, to April 1, 1913, aggregated over 9,000 million gallons. This reduction in consumption in the borough of Brooklyn was such that the average daily consumption for the month of January, 1913, would give a per capita consumption of only 73 gal., which is the lowest per capita consumption for any January since 1894, or for the last 19 years.

The aggregate value of the water thus saved, if figured at meter rates, $133 per million gallons, would be nearly $6,500,000 and the total cost of the work done to effect this saving was about $167,000, which would be reduced to $131,000 if the amount for fines imposed (i.e., $36,000) were deducted.

The per capita consumption for New York City for 1910 (111 gal.) was lower than that of the next five largest cities in the United States, i.e., Chicago, Philadelphia, St. Louis, Boston and Cleveland, for the year 1912; and this in spite of the fact that in New York a floating population of many thousands, not included in the census, is housed, and that there are an equally large number who live outside the limits of New York City, but who work in the city, also left out of the census. If this transient population were considered, the per capita consumption in New York would be materially reduced. Compared with other American cities, New York, therefore, is economical in the use of water, even if we include our waste.

Preventable Waste.—For the purpose of this report, "waste" shall be considered as the quantity of water drawn in excess of that required for the uses already specified, and will be designated as "preventable" when the value of the water wasted is greater than the cost of the methods required to save it, whence it follows that it would be considered non-preventable when the reverse conditions obtain, so that "it will not pay" to save the water, these designations being based exclusively on practical and economical considerations. For "value" must be understood not simply the normal money cost or selling price of the water, but also the increase or decrease due to the condition of the supply at the time. The author has held before that under existing conditions in New York it would not be advisable in making a safe estimate, to assume a larger permanent saving in consumption from the work to prevent waste, than from 15 to 20 per cent., and the results recently obtained seem to bear out these figures.

Reducing Waste.—The following methods are generally employed:—

1. Calling to the attention of consumers the need of checking waste, either for economical considerations or to prevent a threatened shortage on account of inadequate supply, or for both reasons.

2. House to house inspection to detect and repair leaks.

3. Examination for leaks outside of the buildings, in service pipes as well as distribution mains and appurtenances, to locate and repair underground leaks.

4. Metering of all connections where the cost and existing conditions of the supply warrant this measure.

The fourth method cannot under existing legislation be generally applied in New York, nor was it available for the work under consideration. Under the existing legislation, the water department can compel the installation of meters by property owners only in buildings

where water is used for commercial purposes, so that out of a total of 365,000 services, only 86,000 or less than one-fourth, are metered, and of this number 60 per cent. are in the Borough of Manhattan.

Public and Individual Notices.—Public attention was repeatedly called, through the press, to the inadequate supply available in those boroughs in which existing conditions warranted such a statement, the requisite data being also given in support thereof and the imperative need shown of preventing waste in order to avoid a threatened shortage; while a notice printed in English, Italian and Yiddish was delivered at all premises requiring consumers to stop all leaks in their fixtures, advising them at the same time that the department would impose a fine if after the first inspection leaky fixtures were not promptly repaired. These notices, forwarded about the middle of June, 1911, met with instant and efficient response, so that a large reduction in consumption resulted at once.

House to House Inspections.—The larger portion of waste in the city of New York is due to defective fixtures within the buildings, and especially to the water lost from roof and toilet tanks, and leaks from the latter are also the most difficult to detect, as the escape of water is not always apparent to the eye, although the noise made is sufficient, as a rule, to enable the occupant of the premises to detect the leak. Next to leakage of tanks is that from faucets, due either to their being carelessly left open or to need of repairs usually resulting from wearing out of washers.

The Board of Estimate and Apportionment having approved the issue of $100,000 revenue bonds to pay for a house to house inspection, a force of about 100 inspectors was placed in the field in June, with the necessary clerical force to handle the inspection reports, notices of leakage, etc., this force operating under the direction of the water registrar. The Engineering Bureau determined the amount of water consumed before and after house to house inspection, and for this purpose 18 districts were laid out in the borough of Manhattan. The flow into these districts was determined by pitometer measurements, and a record of the reduction in leakage resulting from the inspection was thus obtained. The house to house inspection was continued with full force until September, when the reduction in consumption, together with the increased rainfall, made it unnecessary to prosecute the work as vigorously as in the early part of the summer. At least two inspections were made in each building where leaks were found.

The results of the work done are shown by the following table of consumption, in which the reduction has been approximately apportioned between the work done in stopping leaks in mains and the work done in stopping leaks and waste in buildings:—

	Consumption in Manhattan and Bronx, million gallons per day		Estimated consumption assuming increase of 3 per cent. equivalent to rate of increase in population	Estimated reduction in consumption, million gallons daily		
Month	1910	1911	1911	By stopping underground leaks	By reducing leakage and waste in buildings	Total
January ..	335	334	345	4	7	11
February .	336	331	346	4	11	15
March....	327	327	339	6	4	10
April	326	320	336	6	10	16
May.....	326	310	336	8	18	26
June	329	286	339	9	44	53
July.....	342	287	352	9	56	65
August ..	336	275	346	9	62	71
September	335	277	345	10	58	68
October ..	332	278	342	11	53	64
November	321	271	331	11	49	60
December	333	283	343	11	49	60

Due attention was given to the measurement of flow in pipes and mains outside of buildings, to locate and stop leaks. As investigations made in 1910 had shown some large leaks, especially in mains laid under the East River, and as there was great likelihood of leaks along the river that discharged into it and therefore did not show on the surface, careful measurements were made of the flow of water in various parts of the city to locate these underground leaks, particular attention being given to the river front, and a special division for this class of work was formed, to which were assigned men who had experience in similar work in this and other cities. Broken mains were also found where the loss of water was very great. In one instance, where the broken main lay at the bottom of the East River, the loss amounted to over 3 million gallons per day.

The underground leakage stopped was about 10 million gallons daily, which, if valued at meter rates, would amount in a year to nearly $500,000, while the cost of this work, covering a period of about two years, was $19,000, or say $9,500 per year.

Results Obtained.—The average daily consumption of Manhattan and The Bronx was 331 million gallons in 1910, giving a per capita consumption of 120 gallons. On the basis of the consumption figures for 1910, assuming an increase of 3 per cent. annually due to increase in population, the average daily consumption would increase to 341 million gallons in 1911 and to 352 million gallons in 1912. By the work to check waste, however, the average consumption for the year 1911 was reduced to 298 million gallons daily, or 105 gallons per capita, but the actual reduction was really greater than shown by the above average, as the effect of the water waste work did not show great results until July, 1911, when the reduction reached 65 million gallons daily and was thus maintained on average up to January 1, 1912.

While there was a natural increase in the consumption for the year 1912, the average daily consumption was only 303 million gallons, corresponding to a per capita consumption of 104 gallons. The consumption for the month of December, 1912, averaged 297 million gallons daily, which is less than the average daily consumption for the year 1904. On the basis of the estimated consumption for 1911, 1912 and 1913 some 39,000 million gallons have been saved, which if valued at meter rates, $133 per million gallons, would amount to about $5,187,000, at a cost to the city of about $100,000, exclusive of the fines imposed for leaky fixtures during the time of house to house inspection. The per capita consumption has been reduced from 120 gallons, which was the average for these two boroughs in 1910, to 101 gallons, which is the per capita consumption for the first quarter of 1913.

Through the large reduction in waste effected in Brooklyn, it will be possible to meet all the demands of consumers in that borough up to the time of the introduction of the Catskill supply, without the construction of additional works, and also to furnish several million gallons daily for the supply of Queens, where water is now purchased from private companies.

In Manhattan and The Bronx the per capita consumption has been reduced to 100 gallons, which is lower than the average per capita consumption of every city in this country having a population of half a million or more.

The largest bridge ever exported from England and the largest but one ever built, having a total length of 5,325 feet, is being constructed for use in India.

HAMILTON'S RAILWAY PROBLEM.

The civic authorities in Hamilton have to deal with the opposition of the Toronto, Hamilton & Buffalo Railway in the matter of removing its line from the southern and residential section of the city to a more desirable strip along the bay front. The continual noise and smoke which has been associated with the Hunter Street station has developed an agitation which apparently will not subside without gaining its end. The city is desirous, furthermore, of concentrating all its railways, i.e., the G. T. R., the T., H. & B. (C.P.R.), and the proposed C.N.R. to a common route now used by the former along the water front.

The argument of the T., H. & B. is based upon the likelihood of the change being detrimental to its patronage. It appears that nearly 80 per cent. of the passenger traffic uses the Hunter St. station in preference to the Stewart St. station, while with the union station, which the authorities purpose building on a site near the latter, the patronage would probably be more equally distributed. In consideration of this, however, the city has offered the railway $1,000,000 to move, and City Engineer Macallum has located a proposed line which, in the matter of grades, excels the old route by such a margin as to be a handsome inducement to the railway to accept it.

It is claimed that the Hunter Street route has many disadvantages, from an engineering point of view. Among them the question of grades appears to be the most important, and being over one per cent., the grades have made a name for themselves as a disabling factor to continuous traffic by the stalling of many freights daily. The new route proposed by Mr. Macallum offers a grade of .64.

At any rate, the time has come for the elimination of level crossings, and if the railway authorities do not accept the city's proposal the depression of the tracks will likely ensue, although the company favors elevation, claiming an advantage in cost. It is likely that the Railway Board will shortly be presented with the case, and if it has not the authority to require the T., H. & B. to move, Parliament will likely be approached.

The city's request appears quite reasonable. It offers to indemnify the company for all reasonable loss, to provide a better grade and a route more suitable than the present one. In return the city desires to remove a railway line with its many inconveniences from its residential section, simultaneously eliminating a number of level crossings dangerous to life, detrimental to continuity of street traffic, and unsightly in the extreme.

AN ADVANCE IN ELECTRICAL ILLUMINATION.

Since the introduction of the incandescent lamp, over thirty years ago, the art of illumination has been as apt an example of meritorious study and its fruits as the world has had. From time to time during the interval from the great Edison discovery of the property of carbonized filament, up to the present, many additions of great utilitarian value have transformed the electric lamp from an experiment into a commodity upon which is dependent the health, comfort and general advance of civilization, and the commercial advantages of which alone have rendered possible an indeterminable production from accelerated industry.

Mr. J. S. Leese, a Manchester authority on illuminating engineering, was quoted in April 22nd issue of *The Canadian Engineer* concerning the use of metal filament and its economic value over carbon filament, together with the necessity of change in design and composition of globes and shades to offset the disadvantage of intense brilliancy and its effect upon the eye-sight, which had accompanied the newer filament, and which was considered serious in comparison with the softer light of carbon lamps.

The general displacement of the carbon lamp by that of metal filament has been further retarded to a considerable extent by items of first cost and short life. Its introduction, on the other hand, is due largely to the remarkably small amount of energy which it consumes. In this respect the argument in favor of the metal filament has been so potent as to overcome much pessimistic opinion created by the above-mentioned disadvantages.

The art of electrical illumination has now received an added stimulus in a report from the Schenectady laboratories of the General Electric Company to the effect that a type of tungsten lamp has been scientifically obtained that will consume less than one-half of the energy which the present lamp requires. This is obtained by enclosing the filament in an atmosphere of inert gas, such as nitrogen, the density of which is about the same as that of the surrounding air. It is claimed that the consumption of current in an ordinary tungsten lamp is thereby reduced to one-half watt per candle-power. The effect of this important attainment in the history of illumination is significant.

REVISED FIRE REGULATIONS FOR RAILWAYS.

An amendment to the Dominion Forest Reserves and Parks Act provides that "When a railway within a forest reserve is being constructed or operated by a company not under the jurisdiction of the Board of Railway Commissioners for Canada, the Minister of the Interior may require such company to establish and maintain an efficient and competent staff of fire rangers, equipped with such appliances for fighting fire or preventing fire from spreading as the said Minister deems proper, and to provide such rangers with proper and suitable equipment to enable them to move from place to place along the line of railway.

"The said Minister may require such company to maintain an efficient patrol of the line of railway and other lands in the vicinity thereof to which fire may spread, and, generally, may define the duties of such company, and of the said fire rangers, in respect thereof.

"For the purpose of fighting and extinguishing fire, the said fire rangers may follow fires which spread from the railway, to, over and upon any lands to which they may spread.

"The said Minister may require such company to make returns of the names of fire rangers in its employ in the performance of the said duties, and of the places or areas in which they are engaged."

The above amendment is similar to the provision in the Railway Act, applying to lines subject to the jurisdiction of the Railway Commission. In its last general order, dated July 4th, the Board enacted some important revisions respecting fire regulation. Among them the following differ most from corresponding sections of the old order dated May 22nd, 1912:—

"No employee of any railway company shall open the back dampers of the engine while running ahead, or the front dampers while running tender first, except when there is snow on the ground, and it is necessary to take such action in order to have engine steam properly."

"No such railway company shall permit fire, live coals, or ashes to be deposited upon its tracks or right-of-way, unless they are extinguished immediately thereafter, except in pits provided for the purpose."

"Every such railway company shall instruct and require its sectionmen and other employees, agents, and contractors to take measures to report and extinguish fires on or near the right-of-way as follows:—

"(1) Conductors, engineers, or trainmen who discover or receive notice of the existence and location of a fire burning upon or near the right-of-way, or of a fire which threatens land adjacent to the right-of-way, shall report the same by wire to the superintendent, and shall also report it to the agent or persons in charge at the next point at which there shall be communication by telegraph or telephone, and to the first section employees passed. Notice of such fire shall also be given immediately by a system of warning whistles.

"(2) It shall be the duty of the superintendent or agent or person so informed to notify immediately the nearest forest officer and the nearest section employees of the railway, of the existence and location of such fire.

"(3) The provisions of this section shall apply to all fires occurring within 300 feet of the railway track unless proof shall be furnished that such fires were not caused by the railway."

"Every such railway company shall give particular instructions to its employees in relation to the foregoing regulations and shall cause such instructions to be posted at all stations, terminals, and section houses along its lines of railway. In case said instructions are not also carried in employees' time tables during said prescribed period, or in 'operating' and 'maintenance of way' rule books, they shall, previous to April 1st of each year, be re-issued to all employees concerned, in the form of special instructions."

EDITORIAL COMMENT.

The council of the Canadian Society of Civil Engineers has appointed a committee to prepare a standard specification on reinforced concrete work. The following compose the committee: Mr. C. M. Morssen, Mr. Ernest Brown, Mr. P. B. Motley, Mr. Peter Gillespie, Mr. S. Baulne, Mr. E. S. Mattice, Mr. E. E. Brydone-Jack, Mr. H. M. MacKay, Dr. J. Galbraith, Mr. C. M. Monsarrat, Mr. H. Rolph, and Mr. Walter J. Frances, as chairman.

* * * *

The report of R. C. Harris, commissioner of works for the city of Toronto, relative to the extension of the waterworks system, and appearing in last week's issue of *The Canadian Engineer*, has been considered by the city council and adopted. A mechanical filtration plant to supplement the existing slow sand filtration plant will be established on Toronto Island. One million dollars have been set aside by the council for the installation, and it is understood that no time will be lost in getting the work under way.

FINENESS OF CEMENT AND RATE OF HYDRATION

IMPORTANT RELATION EXISTING BETWEEN THESE QUALITIES—RESEARCH SHOWS VALUE OF HYDRATION AS A TEST FOR FINE GRINDING—LIKELY TO SUPERSEDE THE SIEVE IN THE LABORATORY.

By HENRY S. SPACKMAN,

Consulting Engineer, Philadelphia.

HITHERTO uninvestigated field of research is brought to the attention of engineers in a paper read by Mr. Henry S. Spackman, at the recent convention of the American Society for Testing Materials, at Atlantic City. It brings out well the possibilities of developing a test more thoroughly indicative of the efficiency of grinding, than the present sieving test.

The tests forming the basis of this paper were undertaken in connection with membership in a special committee of the International Association for Testing Materials, to which was assigned the problem of developing a method for the determination of fine flour in cement. The members were advised that there was no pre-determined programme for the investigation, but that each member of the committee was left free to proceed independently to determine which of the two proposed methods, namely, the separation of the cement, either by air or by liquid, into portions, according to the size of the particles—would best serve the purpose, or to develop another method if he thought it desirable that both processes be abandoned and replaced by another more reliable or simple one.

It was decided, in view of the fact that the other members of the committee were studying the separation of fine particles by liquid or air, to investigate what relation if any, existed between fineness of grinding on the one hand, and the decrease in specific gravity and increase in combined or chemically fixed water in the set cement on the other. While it was realized that such a relation, if demonstrated, would give no definite information as to the various percentages of the different sized particles present, it was thought that if either the decrease in specific gravity or increase in water of combination was shown to have a sufficiently constant relation to the amount of cement present in a fine enough state of subdivision to take part in the chemical reactions of setting and hardening, the purpose for which the committee was appointed would be accomplished. It was also thought, in view of the known fact that the chemical composition and degree of burning, as well as fineness of grinding, are important factors in determining the activity of particles of cement of a given size, that the determination of the rate and extent of hydration would be a more correct index of the value of the cement than the mere determination of the percentages of particles of various sizes present, as the effect of chemical composition and burning, as well as of fine grinding, would be included in any conclusions drawn from the determination of the rate and extent of hydration, as evidenced either by the content of combined water or decrease in specific gravity.

While the following tests are in no way conclusive, and are confessedly open to criticism for lack of completeness and crudeness of the methods employed, they are sufficiently concordant to suggest, if not to prove, the existence of a more or less definite relation between the fineness of grinding on the one hand, and the decrease in specific gravity and increase in the content of water of combination of the hydrated cement on the other.

In order to ascertain in a general way the rate of hydration of a normal cement, a commercial sample which passed the Standard Specifications of this society was made into neat briquettes. These were stored 24 hours in moist air, then submerged in water. Briquettes were taken at the several periods indicated in Table I., ground, dried to a constant weight at a temperature of 100° to 110° C., and the specific gravity determined.

Table I.

	Specific Gravity
Cement before gaging	3.17
Gaged Cement:	
24 hr. in air	2.86
24 hr. in air, 24 hr. in water	2.78
24 hr. in air, 6 days in water	2.74
24 hr. in air, 13 days in water	2.63
24 hr. in air, 20 days in water	2.57
24 hr. in air, 27 days in water	2.57

These tests, as might be expected, showed upon first hardening a marked decrease in specific gravity and a gradual decrease as hydration proceeded, up to the 21-day period, after which no decrease in specific gravity was noted, indicating for this particular sample the practical completion of the initial hydration prior to the 21-day period.

In order to ascertain whether the maximum hydration took place when the cement was in the form of a mortar, a sample of the same cement was placed in a test tube with water and agitated for 28 days. This, when tested in the same manner, gave a specific gravity of 2.47 and a loss on ignition of 15.52 per cent., indicating probably the maximum hydration attainable at 28 days under ordinary temperature conditions.

In order to determine the effect of the size of grains on the rate of hydration, another cement having a specific gravity of 3.17 and loss on ignition of 1.70 per cent. was tested. Twenty-gram charges of the cement as received, of the portion of the cement passing the 100-mesh and retained on the 200-mesh sieve, and of the portion that passed the 200-mesh sieve, were placed in test tubes with 50 c.c. of water, and continuously agitated for a period of 24 hours, then dried to constant weight at 100° to 110° C., after which the specific gravity and loss on ignition were determined on the three samples. The results are given in Table II.

Table II.

Cement	Specific Gravity of Hydrated Cement	Loss on Ignition, per cent Before Hydration	Loss on Ignition, per cent After Hydration	Increased Loss by Hydration, per cent.
As received after hydration...	2.94	1.70	5.22	3.52
Passing the 100 and retained on the 200-mesh sieve	3.12	0.65	1.45	0.80
Passing the 200-mesh sieve...	2.84	1.95	6.17	4.22

In order to determine whether exposure to steam at atmospheric pressure would give at short periods hydra-

tion approximating that after a longer exposure in water, the same cement, in the condition it was received, the portion that passed the 200-mesh sieve, the portion passing the 100-mesh and retained on the 200-mesh sieve, and the cement after grinding in a laboratory ball mill for 1, 2 and 3 hours respectively, were made into neat mortar, allowed to stand in moist air for 24 hours, then subjected to steam at atmospheric pressure for 24 hours. The results obtained are given in Table III.

Table III.

Cement	Fineness, per cent passing sieves No. 100	No. 200	Specific Gravity of Hydrated Cement	Loss on Ignition, per cent. Before Hydration	After Hydration	Increased Loss by Hydration per cent.
As received.....	95.6	77.8	2.66	1.70	8.58	6.88
Ground 1 hr.....	99.8	91.0	2.60	1.70	9.41	7.71
Ground 2 hr.....	100.0	97.0	2.59	1.70	9.33	7.63
Ground 3 hr.....	100.0	99.0	2.58	1.70	10.93	9.23
Passing 100 and retained on the 200	100.0	00.0	3.03	0.65	1.60	0.95
Passing the 200 sieve	100.0	100.0	2.63	1.95	10.17	8.22

In order to determine whether subjecting the cement to the action of steam at high pressures and temperatures would show a further decrease in specific gravity and increase in water, of combination, another cement was made into briquettes. A part of these were subjected, after exposure, to moist air for 24 hours and to a steam pressure of 20 atmospheres in an autoclave for 2 hours. Table IV. shows the specific gravity, loss on ignition, and content of carbon dioxide and combined water, of briquettes exposed to moisture in the ordinary way and to high steam pressure in the autoclave.

Table IV.

Cement	Specific Gravity	Loss on Ignition, per cent.	Content of Carbon Dioxide, per cent.	Content of Combined Water, per cent.
Before hydration.....	3.16	0.50	0.40	0.10
Hydrated in moist air for 24 hr.	2.74	6.90	1.25	5.65
After hydration in air and exposed to steam pressure or 20 atmospheres for 2 hr.	2.63	9.60	1.35	8.25

In the absence of any known data showing the specific gravity of a completely hydrated cement, a sample of another brand of cement was taken as received, made into a slurry with 60 per cent. of water, placed in a laboratory ball mill, ground for 8 hours and allowed to stand over night. This cement, on examination next morning, was found to be partially set. Water to the amount of 60 per cent. of the original weight of the cement was added, grinding continued for 8 hours, and a sample taken for analysis. The cement was allowed to stand over night as before. The next morning, while not set, it was found to be too thick to allow of continuing the grinding; and a third addition of water to the amount of 60 per cent. of the original weight of the cement was added, making a total of 180 per cent. of water necessary to make the mixture sufficiently fluid to grind properly. Samples were taken at the expiration of the third day's grinding and at the expiration of the fifth day's grinding. After drying to constant weight at 100° to 110° C., the specific gravity of these samples was determined and analysis made for carbon dioxide and combined water. The results are given in Table V., and indicate a possible specific gravity of completely hydrated cement below 2.3 and a content of chemically combined water of above 15 per cent. It is doubtful whether so great a hydration ever occurs in practice, even after long exposure to water, altrhough the individual particles may have even lower specific gravity.

Table V.

Cement	Specific Gravity	Loss on Ignition, per cent.	Content of Carbon Dioxide, per cent.	Content of Combined Water, per cent.
Before hydration.....	3.12	1.50	1.20	0.30
After 2 days grinding....	2.27	15.50	2.60	12.90
After 3 days grinding....	2.27	16.90	2.50	14.40
After 5 days grinding....	2.27	18.05	2.50	15.85

While the above tests and others made in our laboratory show that a relation exists between fineness of grinding and the rate and extent of hydration of Portland cements, it remains to be determined whether this relation is sufficiently definite to admit of its forming a basis for the development of a test which will replace the use of sieves in the commercial laboratory.

We regret that we were unable to carry out our intention of repeating these tests a sufficient number of times to determine whether the phenomenon of hydration was sufficiently positive to prevent the results obtained being markedly affected by unavoidable variations in the conditions under which the test was made, and also to ascertain whether it was possible for different operators working on duplicate samples to check each other.

We had also hoped, by working on synthetic mixtures of cement containing known quantities of different sized particles, to develop whether any definite relation existed between the content of particles below a certain size and the extent of hydration; also to find an explanation for the anomaly shown by these tests, of the cement being able after hydration had proceeded to a certain point to fix additional water without a corresponding reduction in specific gravity being apparent; also to determine the changes in specific gravity and combined water of cement mortars during long periods of storage under water.

C.P.R. ELECTRIFICATION.

Following the announcement in *The Canadian Engineer* for July 3rd, of the intention of the Canadian Pacific Railway to electrify a section of its line in the Rocky Mountain division, comes a proposal to the city of St. Catharines, from one of the company's representatives, of an electric line from Hamilton to the Niagara River. The city is asked to contribute one-half of the cost of a railway bridge across the old Welland Canal. As an alternative proposition, the C.P.R. is willing to use a bridge jointly with the Canadian Northern Railway, which also intends to build through St. Catharines. In such a case the C.P.R. would pay one-third of the cost and expect the Canadian Northern and the city to bear similar proportions.

The city council looks favorably upon the proposition and will take up the new proposal with the Canadian Northern Railway, which has under consideration the building of a railway and vehicular bridge across the old canal, for which the city is asked to contribute $100,000 and grant a fixed assessment of property, the company to enter the city on a residential street, to which route there is considerable opposition.

The seventh annual convention of the National Society for the Promotion of Industrial Education will be held in the city of Grand Rapids, Mich., October 19-25th inclusive.

WOOD BLOCK PAVEMENTS.

Their Development in the United States, and Specifications Governing Their Use.

By Mr. Geo. W. Tillson,
Consulting Engineer, New York City.

THE earlier wood pavements, including the old cedar block pavements and the first surfacings in the use of chemically treated blocks, is discussed in a paper by Mr. Tillson presented at the Third International Road Congress, London, England. The paper is an excellent resumé of present practice, and contains a summary of the requirements of the specifications of the principal cities of the United States using wood block as a paving material. The following, relating to the construction of wood pavements with treated blocks, is extracted from his paper:—

The city of Indianapolis, Ind., was the first city to take up seriously the question of laying chemically treated wood block. This city in 1896 laid a few streets with blocks of red cedar from the State of Washington. The contract for this work provided that the blocks should be thoroughly dried in a vat at a temperature of 200° F. and then submerged in creosote oil heated to a temperature of over 200° F. and remain there for at least 6 hours. It was estimated that this treatment would amount to about 3 lbs. of oil per cubic foot. The blocks were laid at an angle of 45° with the curb, no provision being made for expansion, and the joints were filled with paving pitch. These streets gave a little trouble on account of bulging caused by swelling of the pavement in wet weather, but not to any great extent. These pavements are still in use and said to be in a splendid state of preservation. These streets were so satisfactory that a more elobarate treatment was undertaken subsequently, the blocks receiving a treatment of 10 lbs. of creosote oil per cubic foot, with certain specification requirements for the oil.

As a result of some investigation in the method of treating blocks there was devised a method which was known as the creo-resinate process. This consisted of impregnating the blocks with a mixture composed of one-half creosote and one-half resin, the early specifications having no requirement for the character of the oil; the idea being that as the creosote was a good preservative, if it could be kept in the blocks they would last until they were worn out, but if used by itself, being so volatile, it would evaporate and the blocks would decay long before they had become destroyed by traffic. The object of the creosote then was to preserve the blocks and of the resin to prevent the volatization of the oil. The first pavement of this character was laid on Tremont Street, Boston, opposite the Common, in 1900. This pavement in the latter part of 1912 was said to be in such good condition that it would probably remain intact for 10 years. In 1902 a sample pavement of one block was laid in Brooklyn, N.Y., with creo-resinate blocks, and later a general specification for same was adopted. This required that the wood should be long leaf yellow pine and that the blocks should be treated with a mixture composed of one-half creosote oil and the other half resin or some other suitable waterproofing material; no attempt was made to regulate the character of the oil. The blocks were to have such waterproof qualities that, after having been dried in an oven for 24 hours at a temperature of 100° F., they should not absorb more than 3 per cent. of water after having been immersed for 24 hours. It was also required that all blocks after treatment should sink in water. The object of requiring the immersion test was that the blocks should be so treated that they would be stable in size, not swelling in damp weather, and so, by bulging, causing deformation of the pavement, nor shrink to an undue extent in dry weather. The requirement that the blocks should sink in water was made because it was realized that it would be somewhat difficult to ascertain how much treatment was given to the blocks, the process being carried out some miles from the city, and it was thought that if they sank in water it would be proven that approximately 20 lbs. per cubic foot had been used or that the blocks were of such a character as not to require so much treatment. The blocks were laid on a ½-in. mortar bed formed of 1 part Portland cement and 4 parts sand, this mortar bed being spread on a substantial concrete foundation. The joints between the blocks were filled with fine dry sand, and the pavement was laid without expansion joints. Almost no trouble has occurred on city streets laid under these specifications on account of bulging.

It soon developed that if much of this class of pavement was used and the same amount of resin as of oil used that the cost of the treatment would be very large. Consequently in the borough of Manhattan, New York City, a specification was adopted by which only 25 per cent. of resin was required, but the specific gravity of the oil was fixed at 1.12. In the course of a few years the question arose as to the propriety of doing away entirely with the resin and using only creosote oil. A committee was appointed by the Board of Estimate and Apportionment of New York City, consisting of the pavement engineers of the different city boroughs, together with the chief engineer of the board and chief engineer of the Finance Department, to prepare a standard specification for wood block pavement. This committee investigated the matter carefully and adopted a specification omitting the resin entirely and having the following requirements for the treatment of the blocks:—

The blocks shall be so treated with an oil elsewhere described that the pine blocks shall contain not less than 20 and the gum blocks not less than 22 lbs. per cu. ft. After treatment the blocks are to show such waterproof qualities that after being dried in an oven at a temperature of 100° C. for a period of 24 hours, weighed and then immersed in clear water for a period of 24 hours and again weighed, the gain in weight is not to be more than 3½ per cent. for pine blocks and 4½ per cent. for gum blocks.

The oil with which the blocks are to be treated shall be a stable, antiseptic and waterproofing oil from which the water has been removed by distillation, and which shall have a specific gravity of not less than 1.12 at 38° C. When distilled in the manner hereinafter described, the oil shall lose not more than 35 per cent. up to a temperature of 315° C. The distillate between 255° C. to 315° C. shall have a specific gravity not less than 1.02, the said specific gravity being taken at a temperature of 60° C.

Some of the manufacturers who appeared before the committee argued in favor of the use of oil manufactured from water gas tar. The committee did not feel that there had been sufficient experience to warrant this, but was willing that a mixture of water gas tar oil and coal tar oil should be used; provided, however, that not more than 50 per cent. of water gas tar oil should be used. The requirement that the distillate between 255° C. and 315° C. should have a specific gravity not less than 1.02 at a temperature of 60° C. was made in order to maintain this limit.

The foregoing gives briefly the development of the specifications for creosoted paving blocks in the East. In other sections of the country the process was about the same, except possibly the provision in New York specifications allowing the mixing of oil from water gas tar with coal gas tar oil for the preservative; and it is extremely doubtful if this provision was ever taken advantage of in New York.

In considering requirements for specifications for wood pavements, there are several points that must be taken into account, some of which the municipal engineers are generally agreed upon and others upon which there is a wide difference. These points are: kind of wood to be used and the size of the blocks, the character of the preservative as well as the amount to be used, the cushion coat on which the blocks are to be laid, the filler for the joints, and the necessity for an expansion joint.

Kind of Wood.—The cost of lumber in the United States during the last few years has been so great that the first cost of the blocks is an important consideration, and while it is generally considered that long leaf yellow pine makes the most durable blocks, it is questionable if other varieties cannot be used either locally or on light traffic streets. The kinds of wood generally admitted by the different specifications are: Long leaf yellow pine, black gum, Norway pine and tamarack. It is probable, however, that if the work is to be done in the far West, some such wood as Oregon fir or Washington cedar could be substituted for these other materials with good results. As has been said, the long leaf yellow pine makes an extremely durable pavement, but it is produced only in one section of the country, so that transportation charges are high, and, when the traffic and local conditions will permit, it is desirable to use a cheaper material.

Some four or five years ago the United States Government laid as an experiment, on a street in Baltimore, a wood pavement made up of a great many different kinds of wood, all treated with 1.09 creosote oil, the idea being to ascertain the relative merits of these different kinds so that a selection of material could be made according to the traffic on any particular street or the availability of any material. The kinds of wood used were long leaf pine, Norway pine, tamarack, Douglas fir, Western larch, white birch and hemlock. The long leaf pine was used to serve as a standard of comparison. The conclusion reached after the examination of the pavement, four years after it had been laid, was that:—

The species used will be tentatively grouped in accordance with the results of this inspection in the order of their value for creosote oil-paving material as follows:

1. Long-leaf pine.
2. Norway pine, white birch, tamarack, eastern hemlock.
3. Western larch.
4. Douglas fir.

In the East, as a matter of fact, the long leaf yellow pine has been used almost entirely up to the present time, the principal exception being black gum. This, however, has not given entirely satisfactory results. The yellow pine, while particularly good as to wearing qualities, is, for that very reason, more slippery and from the formation of the wood liable to split, so that the blocks are often destroyed when taken up to permit of carrying on any underground work. It is probable, however, that on the whole it is the most satisfactory wood for general use.

In the West tamarack has been used slightly, with very satisfactory results.

Size of Blocks.—Not very much difference exists in the practice of the engineers on this point. The first blocks were generally 4 ins. in width, but the more recent practice has been to reduce this width to 3 ins. The permissible length is generally from 5 or 6 to 10 ins., this range in length being given so as not to increase the price by selecting lumber all of one particular width. A difference of $1 per M. ft. in the price of the lumber adds 4 cents per yard to the cost of the pavement. The depth should be governed by the traffic on the street, although, as the blocks are small, they must have sufficient depth to be stable, irrespective of traffic. The indications are from the present experience that the actual wear from traffic on hard pine blocks on an average street is very little, and that, so far as that is concerned, a block 3½ ins. deep would probably last for 20 or even 25 years. Its tendency to split, however, makes it advisable to use a greater depth if the funds will permit.

In this connection it might be said that a small bridge was paved in Brooklyn some years ago with wood blocks, laid upon an old wooden foundation that was extremely irregular and not solid enough to preserve the surface of the pavement under the traffic to which it was subjected. The blocks soon split into pieces averaging about 2 ins. square, but, on account of their not being disturbed, the pavement was very durable, lasting some three or four times longer than the surface which had been previously used.

Character and Amount of Preservative Used.—This is a point upon which there is a great divergence in the practice of different engineers. In determining it, however, it should be understood that the preservative has two functions, one to act as an antiseptic and so prevent the block from decay, and the other to act as a waterproofing material, so that the blocks may remain stable and not absorb water, causing expansion when wet, or allowing too much contraction in a dry spell and thus making the blocks loose. Although an oil of antiseptic properties is desirable, it is probable that if water could be kept entirely from the inside of the blocks there would be no decay. This, however, is an exceedingly difficult matter and probably impossible. It seems desirable that a preservative should be selected that in itself will be stable and remain in the blocks as long as possible, for on residence or light traffic streets the life of a wood pavement will be determined mainly by its ability to withstand decay and not the wear and tear of traffic.

The two main points at issue in the character of the preservative are its specific gravity and its origin. Some argue that the specific gravity of the oil should be approximately from 1.08 to 1.12, the so-called heavy oil, and others from 1.03 to 1.06, the so-called light oil; some also argue that the oil should be a distillate of coal tar, while others would admit oil manufactured from water gas tar. The experience of the past in treating wood demonstrates that an oil from coal tar does make a good preservative, and while the same results might be obtained from a water gas tar product, the experience with this material has not been such as would warrant engineers using it freely. The borough of Manhattan, New York City, is laying an experimental wood pavement, which, among other features, will have blocks laid with coal tar oil and water gas tar oil under similar conditions, both as to material and traffic, making an attempt to determine the relative merits of these two oils. The advocates of the heavy oil recognize that it is not absolutely a distillate oil, and so not similar to what is generally recog-

nized as creosote, but that its specific gravity is attained by combining distilled creosote oil of approximately 1.05 specific gravity with coal tar from which the water, light oils and excess of free carbon have been removed.

In the construction of wood pavements with creosote oil a certain amount of trouble has been caused by the exudation of the preservative upon the surface of the blocks soon after they have been laid, especially in hot weather, causing great inconvenience, particularly to foot passengers, as the surface is often covered with a thick, tarry substance which is exceedingly disagreeable. This exudation occurs when both the light and the heavy oils are used, although the advocates of light oil claim that it occurs much more frequently and to a greater extent with the heavy oils.

Quantity of Oil.—This is a point, too, upon which engineers differ, the quantities used for pine and similar blocks ranging from 14 or 15 lbs. up to as high as 20 lbs. per cubic foot. The quantity of oil used would undoubtedly make a material difference in the amount of exudation in hot weather, but this exudation does not continue for an extended length of time, and it can be taken care of by spreading sand over the pavement surface so as to absorb the exuded material. The action which causes it necessarily brings the material to the surface of the block, so that the pores at the surface must be thoroughly filled, and so cause the block to be as nearly waterproof as it possibly could be, giving after this excessive exudation has ceased a perfect surface so far as absorption of water is concerned. Experiments and experience are necessary in order to determine just what is the required amount of oil to be used. Its cost makes it an important factor in the cost of the pavement, so that it is important that no more should be used than is necessary. At the present time it is considered that on a heavy traffic street less oil can be used per cubic foot than on one of light traffic.

The early Brooklyn pavements referred to were all laid on a cushion coat of sand and Portland cement, mixed in proper proportions and with just enough water to allow the mortar to set. The blocks were rolled down to an even, smooth surface and not disturbed until the cushion coat was thoroughly hard. Recently a cushion of sand has been used in many instances, but the author believes that the mortar cushion gives the best results. It might be claimed that the pavement could be opened for traffic more quickly if a sand cushion were used than with one of mortar, but if traffic is kept completely from the pavement, the blocks can be laid before the foundation concrete has thoroughly set, so that the setting of the cushion coat and the concrete base can go on simultaneously.

Joint Filling.—The practice in this regard has been to use sand, cement and bituminous fillers. The advocates of the sand filler claim that if a fine dry sand is used the joints will be completely filled and that under traffic the surface of the street soon becomes practically homogeneous and that the sand in the joints will absorb a certain amount of the exudation of the preservative from the blocks and so make an absolutely waterproof joint. The advocates of the cement grout filler argue that it is necessary to use this material so that the joints will be absolutely full and remain full. The grout when used is generally made up of a mixture of 1 part of sand and 1 part of Portland cement, with enough water to flow freely into the joints. The opponents of this method argue that unless the pavement is kept free from traffic long enough to thoroughly set, which it is difficult to do, the bond of the mortar is broken, and even if not broken, it has not sufficient strength to resist traffic, so that in either event nothing better than a sand joint is obtained notwithstanding the increase in price. The advocates of the bituminous filler argue that if the joints are filled with coal tar or an asphaltic preparation, or some other similar substance, each joint is practically an expansion joint and that it will allow a certain expansion of the pavement as a whole without any bulging which with the same expansion would take place if a solid filler like sand or cement grout were used. The opponents argue that by the use of this filler, when the preservative exudes from the blocks, as it must to a certain extent, the bitumen in the joints simply adds to the nuisance which is caused by the exudation of the preservative on the surface of the street. In actual practice the sand and bituminous fillers are most generally used.

Expansion Joint.—Although the treatment of the blocks is supposed to prevent the absorption of water, causing expansion of the pavement, in practice it is impossible to have the blocks entirely waterproof, so a certain amount of expansion must take place. Provision for this is made by allowing a space along the curb, which is filled with some kind of bituminous material. For a roadway 30 ft. wide this expansion joint is generally from ¾ to 1 in. in width. No provision is made for taking care of longitudinal expansion, except in the city of St. Louis, although the pavement is continuous for a distance many times the width of the street. No more trouble seems to be caused by expansion in this direction than transversely. Some claim that the bulging is produced by the transverse expansion on account of the crown of the pavement, so that when the pressure is created the resistance to the lifting of the pavement is less than to the compression of the blocks and the result is that the pavement bulges along this line of least resistance. This theory might, to a certain extent, account for the lack of bulging by longitudinal expansion.

In the Brooklyn and Manhattan pavements no expansion joints are provided for, and as far as has been said, very little trouble has been caused by bulging when the material has been yellow pine and when the absorption test has been maintained. The result of this experience would seem to demonstrate that in the climate of New York City, at least, no expansion joint is necessary.

Specifications for Wood Block Pavement.—In the United States there are two organizations which have taken up in detail the matter of wood block specifications. Both are formed of city officials, and one is known as the American Society of Municipal Improvements, the other as the Organization for Standardizing Paving Specifications. This latter organization has had three meetings and has adopted specifications for wood pavements at each meeting; the American Society of Municipal Improvements has adopted specifications at one meeting only.

So that it may be known what the practice is of the engineers of the principal cities of the United States using wood pavements, the requirements of the specifications, as well as those of the two organizations, will be given on each of the general points previously discussed. In this statement the American Society of Municipal Improvements will be designated as "The Society" and the Organization for Standardizing Paving Specifications as "The Organization." It must be remembered that the specifications are constantly changing, but those here given represent the practice in 1912.

Kind of Wood.

The Organization.—Southern yellow pine, Norway pine, black gum, tamarack.

The Society.—Long leaf yellow pine, Norway pine or tamarack.

Borough of Manhattan, New York City.—Southern long leaf yellow pine.

Chicago.—Southern yellow pine and tamarack.

Cincinnati.—Southern yellow pine, Norway pine or tamarack.

Philadelphia.—The same as the organization.

Minneapolis.—Southern yellow pine, Norway pine, Washington fir or tamarack.

St. Louis.—Southern yellow pine.

Size of Blocks.

The Organization.—5 to 10 ins. long, to average 8 ins., 3 to 4 ins. in width, 4 ins. in depth, except on medium traffic and light traffic streets or alleys, where the depths can be reduced to 3½ and 3 ins., respectively.

The Society.—5 to 10 ins. long, to average 8 ins.; 3½ to 4 ins. in depth and width, according to traffic; light traffic streets, 3 ins. in depth.

Borough of Manhattan.—8 ins. long, 3 ins. in width, 4 ins. in depth.

Chicago.—5 to 10 ins. long, to average 6 ins.; 3¾ ins. in width, depth 4 ins., except in special cases.

Cincinnati.—6 to 10 ins. long, to average 8 ins.; 3 ins. in width, 3½ ins. in depth.

Philadelphia.—Same as the Organization.

Minneapolis.—5 to 10 ins. long, to average 8 ins.; 4 ins. in width, 3¼ or 4 ins. in depth.

St. Louis.—Not less than 6 ins. long, to average 8 ins.; 3 or 4 ins. in width, not less than 3½ ins. deep.

Character of Treatment.

The Organization.—Specification A: The preservative to be a product of coal gas, water gas, or coke oven tar, free from all adulterations contained in raw or unfiltered tars, petroleum compounds, or tar products obtained from processes other than stated; specific gravity not less than 1.10 nor more than 1.14 at a temperature of 38° C.

Specification B: Preservative to be a distillate of coal gas or coke oven tar, free from all adulterations, and contain no raw tar, filtered or unfiltered tars or pitches, petroleum compounds, or other tar products; specific gravity not less than 1.03 nor greater than 1.08 at 38° C.

The Society.—Oil to be a coal tar product, free from adulteration of any kind; specific gravity at least 1.10 at a temperature of 38° C.

Borough of Manhattan.—Oil to be a stable, antiseptic and waterproofing oil from which the water has been removed by distillation, and which shall have a specific gravity not less than 1.10 at 38° C. (Further description given in previous portion of this paper.)

Chicago.—Oil to be a distillate oil obtained only by distillation from coal tar; no other material of any kind to be mixed with it; specific gravity to be not less than 1.08 and not more than 1.12 at 25° C.

Cincinnati.—Oil A: The oil to be the best obtainable grade of coal tar creosote, a pure distillate of coal tar and free from admixtures of oils, tars or substitutes that are not pure coal tar; specific gravity to be at least 1.04 at a temperature of 38° C.

Oil B: The oil to be of a coal tar product, free from adulteration of any kind whatever; specific gravity to be at least 1.10 at a temperature of 38° C.

Philadelphia.—The same as The Organization.

Minneapolis.—Oil to be a pure heavy coal tar product only; specific gravity to be at least 1.10.

St. Louis.—The preservative to have a specific gravity of not more than 1.08 at a temperature of 38° C.

Amount of Treatment.

The Organization.—Pine and tamarack blocks to contain not less than 18 lbs., and gum blocks not less than 22 lbs. per cu. ft.

The Society.—20 lbs. per cu. ft.

Borough of Manhattan.—20 lbs. per cu. ft.

Chicago.—20 lbs., probably to be changed to 16 lbs. per cu. ft.

Cincinnati.—18 lbs. per cu. ft.

Philadelphia.—Same as The Organization.

Minneapolis.—No amount specified, but to be so treated as to be impervious to water and to prevent decay.

St. Louis.—16 lbs. per cu. ft.

Each specification contains requirements for the amount of the distillate at certain temperatures, but they do not vary much for the same kind of oil.

Cushion.

The Organization.—Cement mortar composed of 1 part of Portland cement and 4 parts of sand, not to exceed 1 in. in thickness; under special conditions mortar cushion to be omitted and a bituminous coating substituted therefor.

The Society.—Either a sand cushion 1 in. in thickness or mortar 1 in. in thickness made of 1 part of Portland cement and 3 parts of sand.

Borough of Manhattan.—1 in. of sand.

Chicago.—1 in. of sand, or ½ in. of mortar.

Cincinnati.—Either sand or mortar 1 in. in thickness made of 1 part of Portland cement and 3 parts of sand.

Philadelphia.—Mortar, 1 part Portland cement and 4 parts sand, not less than 1 in. thick.

Minneapolis.—1 in. of sand.

St. Louis.—1 in. of sand.

Joint Filler.

The Organization.—Suitable bitumen, or, when the blocks are laid upon a mortar or a bituminous cushion, sand.

The Society.—Sand.

Borough of Manhattan.—Sand.

Chicago.—Asphaltic pitch, cement grout, or sand.

Cincinnati.—Sand.

Philadelphia.—Sand.

Minneapolis.—Pitch.

St. Louis.—Sand.

Expansion Joints.

The Organization.—Not less than ¾ in. along the curb, filled with a suitable bituminous substance.

The Society.—¾ in. along the curb, filled with a suitable bituminous substance; on streets 50 ft. or more in width a second expansion joint similar to the other, separated from the first by a row of blocks; on heavy traffic streets, if deemed advisable by the engineer, expansion joints can be omitted.

Borough of Manhattan.—None.

Chicago.—1½ ins. along the curb, filled with a bituminous substance.

Cincinnati.—Similar to the Society's requirements.

Philadelphia.—¾ in. along the curb, filled with a bituminous substance.

Minneapolis.—1 in. along the curb, filled with pitch.

St. Louis.—1 in. along the curb and at intervals of about 100 ft. across the street at the direction of Street Commissioner, to be filled with a mixture of bituminous material and hard mineral dust.

Since the introduction of treated wood as a paving material it has increased in popularity very rapidly. It was seriously handicapped by the experience of the cities in the past, but, when the officials realized that by chemical treatment the wood would be preserved from decay, it soon came into general use. It has so many good qualities, the chief one being possibly its almost complete noiselessness, and its principal, and perhaps its only bad quality being its slipperiness, that property owners were quick to appreciate it despite its increase in cost over asphalt and other smooth pavements. The slipperiness of wood is experienced only when the surface of the pavement is frosty or damp, or when the grades are excessive. The former trouble exists only in a comparatively few days of the year, and can in a great measure be obviated by proper sanding; the latter can be prevented by judicious action in laying the pavement. The author's practice has been not to lay wood blocks on a continuous traffic street on grades of over 2 per cent.

In considering this question of slipperiness, however, it should be noted that Minneapolis, Minn., which has probably the largest amount of creosoted wood pavement in the country, reports that it has had no trouble whatever from slipperiness, and the city of Great Falls, Mont., also makes the same report. This is exceedingly interesting, when from other cities has come the most positive statements regarding the slippery properties of the pavement.

The popularity of wood as a paving material is illustrated by its present use. The city of New York alone awarded in 1912 contracts amounting to 320,000 sq. yds., while the amount laid in the United States previous to December 31, 1911, was 5,670,000 sq. yds., and it was estimated that from 2,000,000 to 2,500,000 sq. yds. would be laid in 1912. The cost of this pavement varies according to local conditions and specifications, but it averages from $3.25 to $3.50 per square yard, the blocks being 4 ins. deep, laid on a foundation of Portland cement concrete 6 ins. thick.

Repairs.—Very little information can be obtained of the cost of repairs to or maintenance of creosoted wood pavements, because these pavements have practically all been laid under a guarantee by which the contractor is obliged to keep them in repair for five years without extra cost, and also because, after the pavements are out of guarantee, although the repairs are made by the employees of the highways departments, still no exact record of costs has been kept in most cases. The pavement on Tremont Street, Boston, referred to earlier in this paper, has been in use 12 years and has cost absolutely nothing for repairs, and it is stated by the engineer in charge of the Boston pavements that the same is true of some other 14,000 sq. yds. which were laid at about the same time and in the same way. In the borough of Brooklyn, New York City, the first creosoted wood pavement was laid in 1902, without any guarantee, and has cost absolutely nothing for repairs. Pavements that were laid later and have been out of guarantee for 3 to 4 years, have been kept in repair by the borough and an accurate record kept of their cost. Some of the streets have cost absolutely nothing, and the average cost for the entire area out of guarantee has been 1 1/20 cents per yard per year. Many of these pavements, however, have been opened for subsurface work, and the engineer in charge of pavements states that in his opinion practically all of the repairs are due to settlements over trenches, and damage caused by fires, and not to actual wear and tear of traffic. The borough of Manhattan, New York City, has three streets which have been out of guarantee 3 years, one of heavy traffic, one of medium traffic and one of light traffic. The heavy traffic street has cost 7 cents per yard per year, while the average of all has been 6 cents per yard per year; but it should be explained here, as in the case of the Brooklyn streets, that the repairs have been due to wear and tear only on the heavy traffic street, which is a wholesale street in the business section. Repairs on the other streets are due to settlements over trenches, damage caused by fire, and practically nothing to wear and tear of traffic.

The city of Minneapolis, Minn., has 1,000,000 sq. yds. of wood block pavement, the first of which was laid in 1902. The greater part of the material is Norway pine and tamarack. The city engineer states that this pavement has required practically no repairs, the cost of same in 1911 being less than 1/10 cent per square yard. He also states that the street paved in 1902 is in good condition, and looks as if it might last for 10 years longer.

In St. Louis in 1909 repairs to 50,000 sq. yds. of wood pavement laid in 1903 cost $2.10, and in 1911 these same 50,000 sq. yds. cost less than 2/10 cent per yard, so that the total cost of repairing the 50,000 yds. of wood pavement the first nine years they were laid was 2/10 cent per yard. These pavements are all on light traffic streets.

Cleaning.—No definite information seems to be available as regards the relative cost of cleaning wood and asphalt pavements. In 1907, however, a commission was appointed by the mayor of the city of New York to investigate the entire matter of street cleaning. The following is quoted from the report of this commission:—

There is a very marked difference between the quantity of dust left upon the pavements of various kinds. Thus, if we call the average volume and weight collected from the sheet asphalt pavement 100, the relative quantities from other kinds of pavements were:

	Volume.	Weight.
From sheet asphalt	100	100
From block asphalt	130	182
From wood block (note)	332	145
From granite block	1,081	912

Note.—It should be said that the wood block pavement on which the examination was made is one of the oldest of its kind in the city, and its surface, being uneven, caught and held an unusual quantity of dust. Wood block pavement, when comparatively new, should compare favorably with asphalt block pavement in its freedom from dust retaining qualities.

After careful consideration of all the facts available, we estimate the average relative cost of cleaning, equally well, the various kinds of pavement in use in the city under similar conditions of repair, as follows:

Sheet asphalt pavement	100
Wood block pavement (new)	105
Asphalt block pavement	115
Brick pavement	120
Wood block pavement (old)	125
Medina block pavement	130
Granite block pavement	140
Belgium block pavement	150
Cobblestone pavement	3,000

On the assumption of 100 cleanings per year it may be shown that the annual cost of cleaning equally well a mile of each of the pavements named, over what it would be if sheet asphalt were substituted, would be as follows:

Wood block pavement (new)	$ 26.40
Asphalt block pavement (average condition)	79.20
Brick pavement	105.60
Wood block pavement (old)	132.60
Medina block pavement	158.40
Granite block pavement	211.20
Belgium block pavement	264.00
Cobblestone pavement	1,584.00

THE SITE OF THE MONTREAL FILTRATION PLANT.

THE board of engineers, consisting of Messrs. P. W. St. George, J. A. Jamieson and Frank A. Barbour, who were appointed by the City of Montreal at the joint request of the Board of Trade, the Canadian Manufacturers' Association and the Fire Underwriters' Association to enquire into and thoroughly examine the construction of the $5,000,000 filtration plant at Verdun, have submitted their report. In June 19th issue of *The Canadian Engineer*, the facts were given that led up to the appointment of this board. They consisted chiefly of a protest from the contractor, who alleged the site to be most unsuitable to support the heavy construction, and the design to be defective, predicting that further construction was unwise, considering the present condition. His statements were corroborated by a number of prominent engineers whose experiences with municipal installations bearing a close resemblance have been wide, and their opinions regarded authoritative.

The report, which has just been submitted to the city engineer, contains the following statements:—

Our investigation has included personal levelling by one of us to check benches and to determine the present elevation of structures, examination and measurements of the cracks and deformations now existing, studies of the design and of the very complete records prepared by the department engineers of the movements which have occurred, analyses of the soil and tests of the bearing capacity of the ground at various places under conditions, as nearly as possible, the same as those which will pertain when the plant is in operation.

The work has necessarily occupied a considerable period, largely because of the time required to move and set up apparatus, and to permit of observations of the settlement resulting from the loads imposed.

We find:—

(1) That the action of frost on the soil under foundations has been the cause, directly or indirectly, of all damage which has occurred.

(2) That settlement has not been a factor in causing damage up to the present time.

(3) That the design was good precedent, is adequate, and, if properly carried out, the resulting structure will be safe and well adapted to the intended purpose.

(4) That the soil has, and will have, under operating conditions, sufficient bearing capacity to support the loads to be imposed, and that such minor settlements as will occur, either on soil in natural position or on filled areas, will be, as shown by the tests made by us, well within the limit to which the structure may be subjected, without detrimental effect.

(5) That the design and method of construction of the arches is in accordance with good practice, and the superstructure of a type which does not require absolutely equalized foundation loads—this being indicated by the abuse which the superstructure has already withstood without serious final damage.

(6) That the walls, piers and superstructure which were raised, have now practically returned to original position, and except for some spalling of the masonry and the cracks in the division walls, will be, when the full load is on the roof, in practically as good condition as had no movement occurred.

(7) That in addition to the replacement of the damaged collectors, which has already been undertaken by the contractors, the important work necessary to return the structures to a condition practically equivalent to that which would have obtained if no movement by frost had occurred, includes the replacement or repairs of lifted floor slabs and collectors, the repairs of cracks in the division walls, gallery floor and conduit, and the replacement of the retaining wall back of the gallery walls.

(8) That the repairing, by forcing in cement grout under pressure, of structures which have been lifted from a good bearing on the soil, should, preferably, not be undertaken until after the full load to be imposed by the filling over the roof is on the supporting members, but that such grouting of space between masonry and the underlying soil should be completed before water is admitted to the filter units for any purpose.

(9) That since the raising of floors and collectors by frost has introduced abnormal conditions, it is essential that all vacant space be completely filled, or the lifted structures be replaced, and that the success of such filling of voids by grouting, as may be attempted, can only be proved by a test for leakage of the completed filter unit.

(10) That the fulfilment of such test of leakage may be accepted as proof that no damage affecting the working capacity of the filters has resulted from the movements occasioned by frost during the past winter.

We believe it necessary to recommend that, since the contract will not be completed this year, the contractor should be required to protect uncompleted work from the effects of low temperatures during the coming winter, in order to prevent a recurrence of the conditions of the past winter.

We have been greatly aided in our work by Mr. F. E. Field, resident engineer, and Mr. F. Y. Dorrance, principal assistant engineer, and by Mr. McLeod, contractor, who has co-operated in every way possible, and we desire to express our appreciation of the assistance rendered by these gentlemen, and to note the evident fairness of both these engineers and the contractor.

The structures which have already been placed by the contractor indicate good materials and workmanship, and an evident intention to fulfill the terms of the specifications, and we believe that by repair or replacement of those parts which have been damaged by frost, the work can be made entirely acceptable to the city.

The Board of Control will now decide whether the work should be continued by the contractor, or whether the city will undertake the work. Mr. McLeod has expressed his willingness to proceed with the construction, and during the six weeks in which the board of experts executed their careful investigation, he has been continuing the work on other sections of the plant.

MECHANICAL AND ELECTRICAL EQUIPMENT OF THE WINDSOR HOTEL, MONTREAL.

The power equipment for the new Windsor Hotel, designed and installed under the supervision of Mr. Kelsch, Consulting Engineer, is more complete than usual because of the problems to be met. The power plant, which is in charge of Mr. Winkworth, Chief Engineer of the Windsor Hotel Company, is one of the most up-to-date isolated power plants in Canada. The main object of the power plant is to furnish light and heat to the hotel and power for the various motors used in the laundry, for ventilating fans and in other parts of the hotel.

The steam equipment consists of three 200 H.P. Robb water tube boilers each with a heating surface of 2,143 square feet. Two of the boilers are set in a battery and one is installed singly. The boilers, which are built for 175 pounds working pressure, are equipped with Cotton blowers for burning anthracite screenings. This type of boiler consists of two horizontal cross drums with headers which are connected by a main bank of inclined tubes. The drums are connected by two rows of horizontal tubes which complete the path of circulation for the water. At the extreme top, superheating tubes connect the drums so that the steam which is separated in the front drum is thoroughly dried and slightly superheated when it enters the rear drum from which it is piped to the engines.

This boiler is distinguished from other water tube boilers by the large throat area where the front header joins the front drum giving a free and unrestricted passage for the large volume of water and steam passing from the main bank of inclined tubes into the drum. As the drums extend crosswise and the headers are as wide as the length of the drum, there is no contraction at the throat as is necessary in many types where longitudinal drums are used.

Great flexibility is another feature of this new boiler not only from the way it is placed in the setting on the supporting framework, but also because of the construction of the boiler itself. All the tube surfaces run in one direction and the plate surfaces in another, thus eliminating the strains caused in boilers where the longitudinal drums, headers, and tubes are connected rigidly together. A thoroughly modern design, this boiler has ample provision for cleaning, a handhole being placed in the header opposite each tube.

In the engine room of this power plant there are installed three Robb vertical compound engines which are run non-condensing. Each engine is direct-connected to a 150 k.w. electric generator made by the Canadian Westinghouse Company. These engines will operate the generators at 25 per cent. overload for two hours and 50 per cent. overload for one hour. With steam at 150 pounds pressure they will carry the normal load at a speed of 425 r.p.m. These engines are entirely enclosed so that working parts are protected from accident and there is no danger of oil being thrown about the engine room. Every revolving and sliding part is automatically lubricated by a system which consists of a pump and distributing pipes in which a pressure of from 10 to 20 pounds per square inch is maintained. Of the vertical type, these engines have many features which have been very successful in marine practice and modified for stationary practice enable the engines to maintain the speed desired for direct connection.

The electrical equipment had to take into account the fact that for some few years the hotel is under contract with the Montreal Light, Heat and Power Company for current, so that electrical machinery will be used only as a stand-by during this period. This situation called for especial skill in design because the Power Company operates with alternating current generators which means that the direct current switches of the hotel must remain open, except in the event of a shut down on the part of the Power Company. Should this happen the engines in the new power house will be started, the bus bars made alive therefrom and the circuit breakers and the switches on the feeders closed. Signal lamps indicate when the alternating current switches are closed and the direct current switches are open. These signals will enable the station operator to properly manipulate the switches so that the entire lighting system of the hotel will be transferred from the dead alternating current bus to the working direct current.

THE LOTSCHBERG TUNNEL.

The new Lotschberg Tunnel through the Alps was opened officially on June 20. The tunnel is the third longest in Europe, measuring over 9¼ miles, and the cost of the new line was over $17,000,000, the tunnel alone costing nearly $10,000,000. Electric traction will be used on the new route from Spiez to Domodossola, Italy. The weight of the locomotives is 112 tons, and they are fitted with two motors of 3,000 horsepower, weighing 27 tons each, the cost of construction being about $40,500, or twice that of an ordinary steam engine. The overhead or trolley system is employed, a current of 15,000 volts being carried. The locomotives are capable of pulling a train weighing 310 tons up the maximum grades of 27 per thousand at the rate of 31 miles an hour. According to the anticipations of the French press, the new railway will greatly increase the volume of trade between France and Italy, as it will bring the northern and more industrial part of France into direct communication with the peninsula. Italy lacks iron and articles made therefrom, and these have hitherto been imported through the St. Gothard Tunnel route from Germany, but the French iron works in the basin of Briey and Longwy may now be able to compete. At present the imports into Italy from Germany under this head amount to 237,000 tons annually, as compared with 17,000 tons from France.

A new Diesel oil-engine towboat of the Italian navy has a displacement of only 170 tons, but is equipped with a four-cylinder, two-cycle engine of 280 horse-power, running at 250 revolutions per minute. Compressed air at low pressure compared with that required for normal running is used for both starting and reversing. Only a few seconds are necessary for these operations, and a tank on board carries sufficient compressed air for starting or reversing sixty times.

A special bulletin has been issued by the University of Illinois Engineering Experiment Station, discussing the tests and methods employed in measuring deformations of steel and concrete in buildings. Extensive tests have been made on eight buildings in the last three years and they have shown the entire practicability of measuring deformations, or strains in critical parts of a reinforced concrete structure under load. As a direct result of the tests one company has modified its design of the floor slab adjacent to the column cap.

THE ROBB WATER TUBE BOILER.

A description of a water tube boiler that makes any pretensions to completeness would require much space, and would be uninteresting reading. Many of the details of boilers are common to practically all the makes of the water tube type. For this reason it will be only necessary to point out the difference between the Robb water tube boiler and others and explain the reasons for the improved constructions.

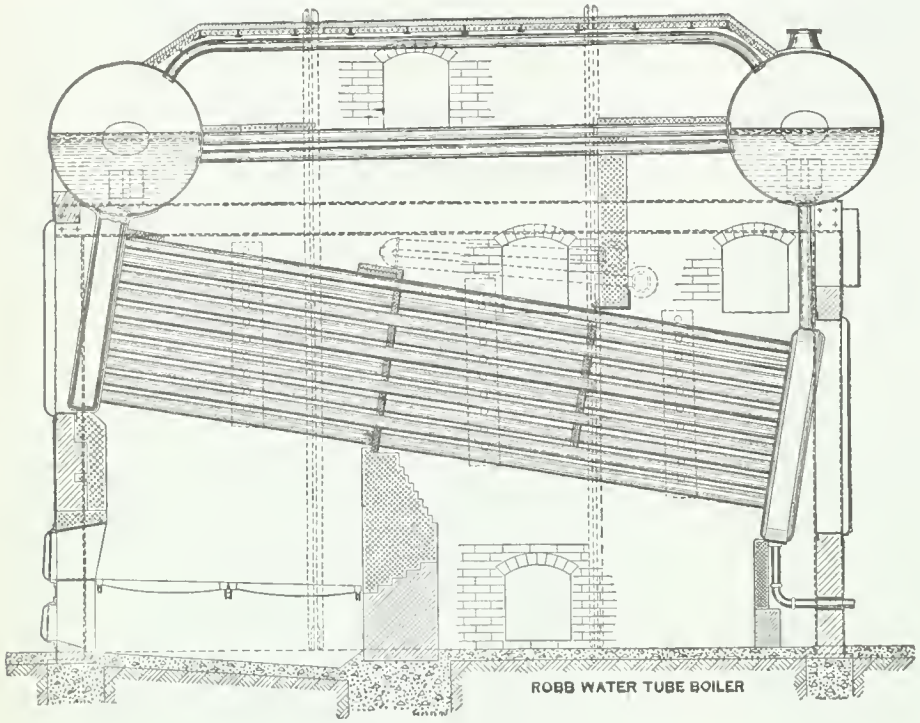

Fig. 1—Section of Robb Water Tube Boiler.

Probably the most distinctive feature of the Robb water tube boiler is the arrangement of parts to give really good circulation. This is accomplished by using two horizontal cross drums and headers, and arranging the connection between the front header and the front drum so that there is an abundantly large passage for the mixture of water and steam as it rises from the tubes just over the hottest part of the fire.

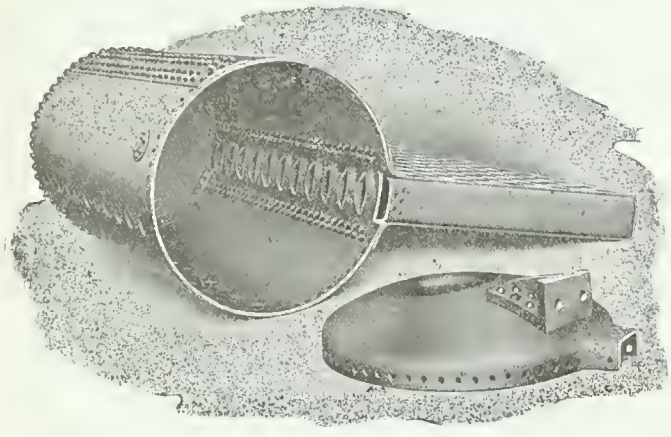

Fig. 2—Showing Construction of Front Drum.

With this construction it is not necessary that the mixture of steam and water pass through a small passage or a single tube for it has the large area provided by the header which extends the entire length of the front drum. By means of a patented throat connection this large passage is obtained without weakening the shell of the drum.

The circuit of the water is completed by connecting the two drums with a double row of horizontal tubes at the water line and by joining the rear header to the rear drum by a row of vertical tubes. This row of vertical tubes at the rear has abundant area for the passage of the water for at this point the water only must be provided for, whereas, at the front of the boiler a larger volume, a mixture of steam and water, must be taken care of.

Flexibility is another feature which has received much attention in the design of this boiler. Flexibility is closely allied to expansion and contraction. In order that such strains may be an absolute minimum in the above type of boiler, all the tube surfaces run in one direction and all the plate surfaces in another, thus avoiding the disastrous results often experienced from unequal expansion and contraction between thin tubes and thick drum plates when both run lengthwise and are connected rigidly.

The boiler is carried on a steel framework entirely independent of the brickwork. The front drum is the only part that is fixed in position. The rear drum is supported by brackets resting on rolls and the rear header is suspended by the long vertical tubes which connect the rear header and the rear drum. It is, therefore, free to swing back and forth and take care of the expansion and contraction of the main bank of tubes.

Dry steam is assured at all times, because the steam is not taken from the same drum in which it is separated from the water. The mixture of water and steam in this type of boiler enters the front drum, the steam separating out passing through the superheating tubes at the extreme top to the rear drum from which it is taken to the steam mains. The water which separates from the mixture flows to the rear drum through the horizontal tubes and mixes with the cooler entering feed water.

One other point is worthy of notice; that is, the arrangement for cleaning the inside of the tubes. The water

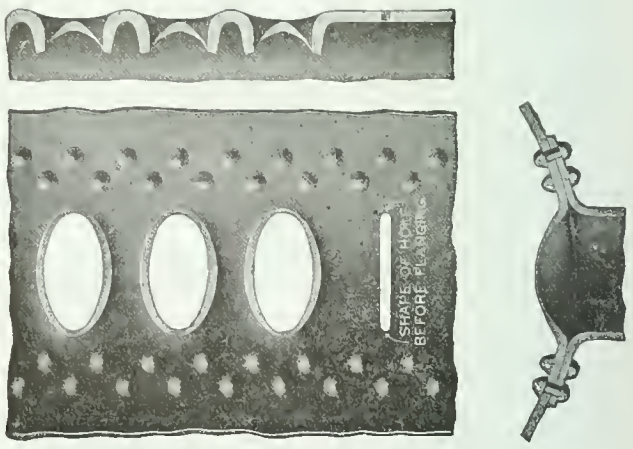

Fig. 3—Showing Throat Connection to Front Drum.

tubes are absolutely straight, as water tubes should always be, and to clean them it is only necessary to remove the front hand-hole plate opposite a tube, insert a scraper and push the sediment back into the rear header from which it drops into the mud chamber at the bottom. The hand-hole plates are oval and there is one opposite each tube. This greatly

increases the convenience in cleaning over those boilers having round hand-hole plates, which require that they be worked hand-over-hand amongst the stay bolts.

In all respects the new Robb water tube boiler, which is made by the International Engineering Works, Ltd., fulfils the requirements of the rules formulated by inspection and insurance companies and government officials. Although rated at 10 square feet of heating surface per boiler H.P., they have proved under severe tests to have a capacity 50 to 100 per cent. over rating without injury.

AMERICAN ROAD CONGRESS IN DETROIT.

How to systematize the purchase of road equipment and materials will be explained in a paper to be read by Henry G. Shirley, chief engineer of the Maryland State Roads Commission, at the American Road Congress which will be in session during the week of September 29 at Detroit, Michigan. This paper deals with one of the many important subjects to be treated by experienced engineers, public officials and road contractors at the big meeting. On account of the fact that the Maryland Commission has been working out the problems of good road administration in a most painstaking and thorough manner, Mr. Shirley's paper should be a most welcome contribution.

Col. E. A. Stevens, state highway commissioner of New Jersey, will have a paper at the Congress on treatment which he has found most effective for worn out or raveled macadam surfaces. New Jersey was the first State to adopt the State aid plan for road construction and consequently had a large mileage of water bound macadam roads prior to the advent of the motor vehicle. The problem of the State highway department has therefore been particularly along the lines of adopting the old roads to new traffic conditions.

The merit system in road administration will be aptly presented in an address by President John A. McIlhenny of the United States Civil Service Commission and will undoubtedly attract nation wide attention as it is a notorious fact that political favoritism and indifference characterize the administration of our public roads so generally as to cause a loss estimated by some experts as high as $40,000,000 a year. No more serious drawback to the progress of road improvement exists than the incompetent management of the roads and it is hoped that Mr. McIlhenny's address will help in securing much-needed reforms.

Other addresses and papers will be given by Capt. P. St. J. Wilson, State Highway Commissioner of Virginia; W. S. Keller, State Highway Engineer of Alabama; A. R. Hirst, State Highway Engineer of Wisconsin; Frank F. Rogers, State Highway Commissioner of Michigan; and many others prominent in the practical field of road construction and maintenance.

The Congress is held under the presidency of Logan Waller Page, director of the United States Office of Public Roads and comprises the conventions of the American Highway Association, the American Automobile Association, the Michigan State Good Roads Association, a large session under the auspices of a committee from the American Bar Association and other special sessions held under the auspices of the leading organizations identified with the road movement. The attendance at the first congress held in Richmond, Virginia, 1911 was 1,200; at the second congress held at Atlantic City in 1912, 2,000. This year the ratio of increase will be supplemented by an attendance of at least 2,000 at the State Good Roads Association, so that the management conservatively estimates the attendance this year will be over 5,000 delegates and members.

The National Association of Road Material and Machinery Manufacturers will be represented by a great commercial exhibit of road machinery and materials and arrangements have already been made for an exhibit of the remarkable collection of road models owned by the United States Office of Public Roads and for interesting exhibits by many of the States, cities and educational institutions.

MAINTENANCE OF PURE WATER IN SASKATCHEWAN BY PROVINCIAL BUREAU OF HEALTH.

As the present excessive death rate from typhoid fever in Canada is admittedly due to neglect in protecting surface waters from pollution, it may be interesting to record what measures are being adopted by the Saskatchewan government, through the Bureau of Public Health, towards the conservation of the purity of provincial waterways.

The Bureau of Health has continued to impress on all municipalities the grave lesson to be learned from the lack of foresight of older communities, and the towns and cities have been quick to realize that a system of sewerage is not a convenience but a sanitary necessity, and that the very object aimed at in its installation, namely, the protection of the public health, may be defeated if some efficient treatment is not provided to render the effluent incapable of supporting the germs of disease.

As a result of this policy, there are at present eight sewage disposal plants in operation in Saskatchewan. In seven of these installations, the sewage is treated by biological filtration, in addition to sedimentation, and a filter is being added to the remaining plant this year. Further, plans for ten additional sewage disposal installations for various towns have been submitted to the Bureau, and these works should be in commission before the end of the year.

This means that at the close of the present year the sewage from all the cities and thirteen towns in the province, representing about one-third of the total population, will be rendered practically harmless before being discharged into the water courses. When it is considered that in 1912 there were only five sewage disposal plants in operation, capable of treating sewage from a population of 16,500, it must be evident that municipalities are co-operating with the Bureau of Health in the improvement of the condition of provincial waterways.

Systematic supervision and inspection is made of the existing sewage disposal works by the engineering officials of the Bureau, and suggestions offered, which are calculated to give a higher standard of efficiency in each new installation. The Bureau of health has, up to the present, concentrated its efforts in the prevention of stream pollution by municipalities, but now that the towns and villages are alive to the consequences of neglect in matters of sewage treatment, it is the intention of the officials to direct their energies towards the large section of the population who, individually rather than collectively, contaminate surface water supplies. There are numerous settlements, camps and villages along the streams and creeks, which have no system of disposing of their sewage, but simply use the nearest watercourse as a common sewer. Such streams being subject to direct pollution from fecal matter entering the water from isolated houses or camps, are capable of carrying disease through the large areas of the province which they traverse, and is largely responsible for the outbreaks of typhoid which have occurred in the province. The possibility of some such direct pollution being present in a river, which is supplying unfiltered water to one

of the larger towns, is only one instance of the viligant guard which must be kept over the streams. With this in view, the Bureau of Health is about to commence a thorough and exhaustive inspection of the various watercourses throughout the province.

If immunity from typhoid is to be aimed at in Saskatchewan, all possible sources of domestic water supply must be under constant supervision, and this can only be accomplished by making a systematic survey of the entire province.

There are two periods in the history common to all rivers which serve as a source of water supply for the populated districts through which they flow. First, that of gradually increasing pollution from domestic sewage and trade wastes, which, unnoticed, continues to render the water dangerous, until a severe outbreak of typhoid fever is reported at some point down stream, involving the loss of perhaps scores of lives. Then follows a period of investigation into the source of contamination, and legislation to prohibit further pollution of the river in question. This history has repeated itself in practically every civilized country, and at the present time a bill is receiving its second reading at Ottawa, the object of which is to prohibit further pollution of Dominion waterways. A special committee has been elected to report on the subject. Further, the Commission on Conservation is making careful inquiry into the question of stream pollution, and inviting the provincial authorities to co-operate in safeguarding the public health. A third commission is seeking to solve the problem from an international standpoint.

It is to be regretted that several outbreaks of typhoid fever, accompanied by many deaths, should have been necessary to awaken general interest in the increasing pollution of our rivers and streams. Generally speaking, it is an accepted fact that the typhoid death rate of any country may be taken as the index for the condition of its streams and rivers.

The average death rates from typhoid fever in Norway, Sweden, Holland, Germany, Switzerland and Great Britain vary from 6.2 to 12.8 per 100,000 of the population. In Canada the typhoid death rate is 35.5. Unfortunately, the province of Saskatchewan has contributed in a large measure to this high death rate for the Dominion. Within recent years outbreaks of typhoid fever have occurred at Moose Jaw, Saskatoon and Prince Albert. The number of cases in Regina has never been so great as in the other cities. This fact is significant when it is considered that Regina receives its water supply from underground sources.

Conditions have greatly improved within the last few years, however, and the death rate from typhoid fever in the province should show a marked decrease this year. Saskatoon and Prince Albert have both installed efficient filtration plants, and Moose Jaw has abandoned a surface supply in favor of water from springs at Caron, the construction and plant of whose system was dealt with in *The Canadian Engineer* for March 6th, 1913.

A NEW ROAD MATERIAL.

With a view of obtaining a road surface which will give a better resistance to automobile traffic, experiments are being made again in France with a road-bed material consisting of a mixture of "iron straw," or iron in the shape of a wiry or fibrous mass, together with cement mortar and sand. Such material is called "ferro-cement," and it appears from tests that it is giving good results. The iron is specially prepared by suitable machines, and it is claimed that the resulting material is not over-expensive.

COAST TO COAST.

Regina, Sask.—The parks and playgrounds committee of the Town Planning Association are endeavoring to have more playgrounds established in the city, with the required equipment. The city of Regina has already spent thousands of dollars on this work.

Ottawa, Ont.—Preparations are being made to commence immediately the extension of the refinery at the Dominion Mint. A vote of $40,000 for that purpose was passed last session, as the refining of Canadian gold has gradually increased, and made necessary an extension of the present refinery. Last year the amount of Canadian gold was $1,168,823. Government architects will have charge of the work.

Toronto, Ont.—The proposal to use the Niagara River from Lake Ontario to a point near Queenston in connection with a new Welland Canal, which would be built from that point to a Lake Erie outlet, was presented before the Toronto Harbor Board recently by Ald. L. Pitt, of Niagara Falls, Ont., who is behind the project. Should this plan be adopted it is claimed that about $30,000,000 would be saved over the cost of the new Welland Canal proposed by the Government. Ald. Pitt, after showing the plans to the harbor board, stated that it was his intention to at once lay the question before Hon. Frank Cochrane, Minister of Railways and Canals.

Ottawa, Ont.—The Department of Public Works is investigating the utility of railway marine docks. Mr. Arthur St. Laurent, Assistant Deputy Minister of Public Works, has returned from Boston, where he inspected the Crandall engineering works, makers of this style of docks. For vessels or steamers up to 10,000 tons they are well suited, the ship entering a cradle and being quickly drawn up high and dry by an engine. The average cost is about $60,000, and as many as four vessels can be accommodated at once. Mr. St. Laurent was favorably impressed, and will recommend the railway docks for places where it is not desirable to go to the heavy expense of a graving or floating dock.

Ottawa, Ont.—Either the increase in population of the city, consequently causing an increased demand, or the percentage of waste has abnormally increased, is the reason for the high average of the water consumption reached this year. Acting Waterworks Engineer Wm. Storrie has reported to the waterworks committee that the average daily consumption last year was 17.7 million gallons daily, while so far the average this year has touched 18.6 million gallons per day. The figures this year for maximum million gallons daily are: January, 19.6; February, 19.7; March, 20.2; April, 19.1; May, 19.4; June, 20.0; July, to date, 21.5. The work on the pitometer survey for the detection of wastes is going ahead satisfactorily, and a number of small leaks have been detected and quickly repaired.

Vancouver, B.C.—Advertisements calling for tenders for the new dock to be built at Vancouver by the Dominion Government have been sent out and plans and specifications are being mailed to this city. Information to this effect was received recently by Mr. H. H. Stevens, M.P., in a telegram from Mr. J. B. Hunter, Deputy Minister of Public Works, Ottawa. The Government wharf will be located at the foot of Salsbury Drive, and will cost about $750,000. Construction work will probably start about the middle of next month, and the work is expected to take twelve months. The dock will be approximately 1,000 feet in length and 300 feet wide, with three railway tracks in the centre and concrete retaining walls on each side. The lowest depth of water at the land end of the dock will be thirty-five feet, thus enabling vessels of large draft to berth at all stages of the tide. A large

number of tenders are expected to be submitted, as the contracts are open to the world.

Windsor, Ont.—"Think of how few persons in the United States will be benefited by the Panama Canal, on which we are spending $420,000,000, and then consider the great benefits to be derived by the hundreds of thousands of people clean across the country from the Lincoln Highway, stretching from the Atlantic to the Pacific," said E. P. Brinegar, secretary of the Argonaut Trail Committee, of San Francisco, in Detroit recently. The Argonaut Trail Committee is the dynamic California force in the western movement that is aiding the ocean-to-ocean project as a memorial to Abraham Lincoln, and fostered by the Lincoln Highway Association. "The Panama Canal, for which every citizen must pay his share of the cost, will bring untold benefits to England and Europe, enabling commercial interests there to gain easy access to the Orient," Mr. Brinegar continued. "It will make it easy for Atlantic coast shippers to reach the Pacific coast, and vice versa. But will it help the people of Michigan, Ohio, Indiana, Iowa or any point in the middle or far west? Yet the Lincoln Highway, of which our own Argonaut Trail, we hope, will be a part, will pass the front door of uncounted multitudes of people, and will be perpetually at their service. An ocean-to-ocean road built for endurance is a national need. There are men in Nevada and in other States to-day who must haul water fifty miles over rough and burning trails. And in States far more opened to civilization the need is equally great."

Vancouver, B.C.—Many roads about Greater Vancouver are being opened, cleared and graded and put in shape for traffic by the Provincial Government, under the supervision of Provincial Road Superintendent, Mr. E. McBride. The Provincial Government has appropriated $25,000 to the municipality of West Vancouver for the improving of Marine Drive within its boundaries. To connect with the improved thoroughfare in the new municipality the Government is having Robson Road, from the west boundary of the city of North Vancouver to Capilano Creek, cleared and graded and put in good condition for all kinds of vehicular traffic. When all the roads on the north shore now in course of repair and improvement are finished, Road Superintendent McBride says that the districts on the north shore of the inlet will have excellent highways; in fact, nowhere in the province will there be better roads, and the scenery along the whole route from the North Arm to Howe Sound will be an attraction to tourists and others. Mr. McBride has charge of all road work in the Westminster district as far up the coast as Pender Harbor. In the district bordering this arm of the gulf much work is also being done by the Government in improving the roads. Mr. McBride in his periodical trips of inspection superintends all construction work. In numbers of cases after the roads have been cleared and graded the municipalities macadamize the surface and in other ways treat the portion of the roads which are most used for traffic.

Ottawa, Ont.—The Government is reported to be about to appoint a water power commission to be known as the St. Lawrence and Great Lakes Commission, for the purpose of studying the whole question of water power development from the head of the Great Lakes to Montreal. The probable members of the commission are given as: Professor McLeod, McGill University; Mr. Arthur Surveyer, Montreal; and Mr. C. R. Coutlee, of the Public Works engineering staff. It is expected the St. Lawrence and Great Lakes Commission will be engaged upon its task for several years to come. This work may result in the establishment of a permanent bureau dealing with water power questions to which the Government can go for reference. The Canadian section of the International Waterways Commission will have the use of the reports of the new commission.

Vancouver, B.C.—On a general inspection trip of Western lines of the Canadian Pacific Railway system, Mr. J. G. Sullivan, chief engineer for Western lines, arrived in the city recently. The question of utilizing oil as fuel instead of coal, as at present used on locomotives on the Cascade division of the Canadian Pacific Railway main line between Vancouver and North Bend, is one of the principal subjects to be taken up by the chief engineer with local traffic officials. Oil is used as fuel on other sections of the line in British Columbia, and an extension of the use has been planned in accordance with the general policy of increasing the efficiency of the service. Tanks for the fuel have been located at Port Moody, and the idea was mooted some time ago of having the oil piped to Coquitlam, where the Canadian Pacific Railway shops are now established. Mr. F. F. Busteed, engineer in charge of the double-track operations in British Columbia, accompanied Mr. Sullivan to the city from Kamloops, and will take up a number of questions with him before he leaves again for the East. Mr. F. W. Peters, general superintendent for the British Columbia division, and Mr. H. Rindal, district engineer, will accompany Mr. Sullivan on his inspection trip of the main line and branches in this Province next week. The various terminal improvement schemes, in the way of new docks, bridges and new depot, which are now being actively prosecuted by the Canadian Pacific Railway in Vancouver, will be inspected by the chief engineer, and he will also discuss the gigantic tunnel scheme in the vicinity of Rogers Pass with local officials.

Victoria, B.C.—Just what shall be done towards putting an end to harbor pollution, a subject on which there has been of late numerous suggestions made to the city council, is a question which has been under investigation by the health officials of the city. City Sanitary Inspector Lancaster has, as a result of his investigations, reported to the medical health officer to the effect that the chief source of trouble is from sewerage effluent from various vessels berthing at the wharves, and for this he can suggest no remedy. Another serious phase of the question is the dumping into the harbor, from vessels, of garbage, kitchen refuse, boxes ,etc., This can be remedied if those in charge of the vessels would insist that the rubbish now regularly deposited in the harbor be retained until the ships are well at sea. What can be done relative to the obnoxious odors which arise when the tide is out is another matter to be dealt with. The disagreeable odor arising from the mud flats below the Causeway during low water can apparently only be obviated by the dredging out of these banks so that at low water there will still be water over the mud. Whether the retaining walls now there would be affected if the present flats were dredged is a question which would have to be investigated. Either dredging would have to be resorted to or a smaller and lighter wall built some distance from the present walls and the space between filled in. Medical Health Officer Hall will shortly have a report before the city council going into the whole matter, and will make certain recommendations for the council's consideration.

Ottawa, Ont.—Experiments are to be made by Controller Nelson and Engineer Currie in the use of tarvia and oil on roads instead of water sprinkling. While the work this year will not be carried on in an extensive scale, it will form the basis of a report for next year's city council. It is estimated that the macadam and ordinary dirt streets can be treated with tarvia or oil for about ten thousand dollars more than the street sprinkling costs this year. The advantage of the extra expenditure will be more satisfactory work, and in addition it is claimed the oil and tarvia will pay the extra cost in added life of the roadway and lessened repairs. So far, tarvia, oil and similar substances have not been used to any extent by any city on asphalt pavements, and it is not proposed to experiment with them here. Water would

still be used, but instead of the present sprinkling carts, up-to-date flush tanks are proposed. Controller Nelson intends to shortly visit Detroit and Rochester to inspect the kind of streets they have there and the methods of treating them.

Montreal, Que.—Councillor W. G. M. Shepherd, of Westmount, has returned from an extensive road tour of New York and the New England States, in which he was the guest of Lorne Webster. Mr. Johnson, of the Department of Marine and Fisheries, accompanied the party. "American roads certainly show a vast improvement on Canadian ones," stated Mr. Shepherd. "Our trip, which was from Ogdensburg to Kennebunk Beach, Me., included an itinerary of nearly five hundred miles; and the worst part of all this stretch was much better than the majority of the roads around Montreal. In my opinion we are losing thousands of dollars every year in American tourists alone by our lack of automobile roads fit to run a car over. The fact that the highways bill lost out in the Senate should not prevent the Provincial Government from building a highway, say, from Montreal to Quebec. Nothing would advertise our province so well."

Toronto, Ont.—"United States Government aid will mean railroad construction to the extent of upward of one thousand miles," declares Falcon Josleyn, of Fairbanks, in a hearing on the Alaska Railroad bill before the house committee at Washington on territories. The Canadian Government is building the Grand Trunk Pacific across the continent to the Pacific Ocean through a country not nearly so productive or rich as Alaska for a distance of more than three thousand miles, and we are here to ask Congress to authorize the construction of only a little more than seven hundred miles of road. Our territory needs railroads for development of its natural resources, and we ask favorable action on our bill." Mr. Josleyn gave the committee detailed information about mineral and agricultural resources of Alaska, and also some information about the poor transportation facilities. The committee appeared impressed with his testimony, and questions asked indicated a disposition to help railroad construction in the territory.

PERSONAL.

Mr. E. J. WHITTAKER, of Seaforth, Ont., has received an appointment to the palœontological staff in the geological surveys branch of the Department of Mines, Ottawa.

Mr. T. BROCKMAN, landscape architect, of Berlin, presented an address on the subject of "Town Planning" to a recent meeting of the Regina Engineering Society.

Hon. FRANK COCHRANE, Minister of Railways and Canals, is on a tour of inspection of the Trent Canal. He is accompanied by W. A. BOWDEN, B.A.Sc., chief engineer for the department.

Professor S. A. MITCHELL has been appointed director of the Leander McCormick Observatory at the University of Virginia. Graduating from Queen's University in 1894, he secured a gold medal in chemistry for his spectacular attainments in research work. He has for some years held a professorship in Columbia University, New York.

Mr. C. W. GENNET, Jr., has assumed the duties of treasurer and manager of the Messrs. Robert W. Hunt & Company, Limited, at their principal office in the McGill Building, Montreal. Mr. Gennet has heretofore been in charge of the parent company's bureau of inspection of rails and fastenings at the home office in Chicago.

ARTHUR H. BLANCHARD, M. Can. Soc. C.E., Professor of Highway Engineering in Columbia University, has returned from Europe, where he attended the London Congress of the Permanent International Association of Road Congresses as a delegate from the State of New York and several societies. After the adjournment of the Congress Professor Blanchard made an investigation of various pavements and roads in England, France and Germany.

OBITUARY.

Mr. J. H. New, of Toronto, for many years president and managing director of the Hamilton and Toronto Sewer Pipe Company, died on July 17th after an illness of several weeks' duration. Mr. New had many business interests in the city and was long associated with manufacturing activities in Toronto and Hamilton.

Mr. N. G. H. Burnham, in charge of one of the sections of the Manitoba branch of the Hydrographic Survey of Canada, was drowned in the Valley River, near Dauphin, Manitoba, on July 15th, through the capsizing of a canoe. Mr. Burnham and his party were attempting to make a particularly difficult crossing at the juncture of two streams when the accident occurred. The unfortunate young engineer was a son of Dr. G. H. Burnham, of Toronto. He matriculated from Upper Canada College into the Royal Military College, Kingston, in 1906. On the completion of his course in the Royal Military College, in 1909, he entered the faculty of applied science at Toronto University, graduating with the degree of B.A.Sc. in 1912. For the past year and a half he has been engaged in hydrographic survey work in Manitoba and Saskatchewan.

COMING MEETINGS.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Honorary Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

A joint annual meeting of the Canadian and American Peat Societies will be held at Montreal, Canada, on August 18th, 19th and 20th, 1913.

The first International Exposition of Safety and Sanitation ever held in America will take place in New York City, December 11th to 20th, 1913, under the auspices of the American Museum of Safety. Safety and health in every branch of American industrial life, manufacturing, trade, transportation on land and sea, business, engineering, in all of their sub-divisions will be represented at this exposition. It will be the first step toward making a representative exhibition of the progress of safety and preventive methods in America.

READERS SHOULD NOTE THE REMOVAL OF THE LIST OF CANADIAN TECHNICAL AND MUNICIPAL SOCIETIES FROM THIS PAGE TO PAGE 94, IN THE REFERENCE SECTION OF **THE CANADIAN ENGINEER.** BY THIS CHANGE, ALMOST AN ENTIRE PAGE OF READING MATTER IS ADDED WEEKLY.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found sommaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

19709—May 30—Establishing collection and delivery limits of express companies in city of Portage la Prairie, Man., and rescinding Order No. 14882, dated Sept. 16th, 1911.

19710—June 27—Postponing, until Aug. 1st, 1913, the effective date of the modifications of Rule 7 G.T.R. special freight tariff, C.R.C. No. E 2374, I.C.C. No. 1660, contained in supplement Nos. 5 and 8, respectively, thereto, and of Rule No. 33, C.P.R. local freight tariff, C.R.C. No. E. 2141, I.C.C. No. E. 1288, contained in supplement Nos. 9 and 6, respectively, thereto.

19711—June 30—Amending Order No. 19546, dated June 10, 1913, by striking out words "distant signals" in second line of paragraph 2 of operative part of Order.

19712—June 30—Directing G.N.R. put into force on shipments of ore, in carloads, from Saimo to Nelson, B.C., following additional rates:—$1.10 per net ton when valuation does not exceed $15 per ton, $1.15 per net ton when valuation does not exceed $20 per ton; said rates to be made effective within 30 days from date of this Order.

19713—June 27—Directing C.N.R. move crossing lying to south of south switch in northerly direction, to a point 60 ft. from south switch, and grade road from said crossing to loading platform, to satisfaction of an engineer of Board; cost of grading road be borne and paid by Railway Company.

19714—June 30—Authorizing G.T.R. to reconstruct bridge No. 99 over public road between lots 16 and 17, in con. 3, Tp. Ray, at mile post 161.10, 9th Dist., 2.90 miles east of Midland.

19715—June 30—Approving revised location G.T.P. Branch Lines Co., station at Ruthilda, Sask., in Sec. 3-34-18, W. 3 M.

19716—June 30—Authorizing C.P.R. to use subway over Main St., at Kenora, Ont.

19717—June 28—Authorizing C.P.R. to construct following bridges: 1, 22.3 Toronto Sub-Div., Ont. Div., near Peterborough station; 2, 21.8 Toronto Sub-Div., Ont. Div., near Botulf station, and 3, 19.4 Newport Sub-Div., Eastern Div., near Sutton station.

19718—June 27—Authorizing G.T.P. Branch Lines Co. to operate trains over crossing at Arcola branch of C.P.R. at Griffin, Sask., without their first being brought to a stop.

19719—June 30—Directing that within 60 days from date of this Order, C.P.R. move stock pens at Shelburne to west side of its tracks, pens to be long enough to place not less than four cars at one time, each pen to have a gate opening to loading platform, upper deck loading chutes to be provided for sheep or hogs at each end of pens.

19720—June 30—Authorizing C.P.R. to construct spur for Cockshutt Plow Co., Ltd., Calgary, Alta., spur to be completed within three months from date of this Order.

19721—June 30—Relieving C.P.R. from providing further protection at highway at mileage 22.79 from St. Martin's Jct., Que.

19722—June 30—Authorizing T., H. & B. Ry. to construct spur into lands of John McInnes, Hamilton, Ontario.

19723—June 27—Refusing application Eustis Mining Co. for an Order amending Canadian Car Service Rules to provide for five days' free time at Sorel, Que., on copper-sulphur ore shipments for transfer to vessels.

19724—June 30—Authorizing C.P.R. to construct spur for Wells & Emerson, Port Arthur, Ont., spur to be completed within three months from date of this Order.

19725—June 30—Approving proposed change in location of C.P.R. siding for William Davies Co., Ltd., near intersection of Front St. and Esplanade Ave., Toronto, Ont.

19726—June 30—Approving revised locations of portions of C.P.R., constructed line, Shuswap Sub-Div., mileages 0 to 25, Revelstoke to Taft, B.C.; 2, authorizing company to construct revision in grade of line and in grade of highway crossings, as constructed, on said line; 3, authorizing company to construct, by means of grade crossings, additional track (double track) across nine (9) highways between mileages 0 and 25.

19727—July 2—Extending until August 31st, 1913, time within which C.P.R. complete spur adjoining Neebing Avenue, Fort William, Ont.

19728—June 30—Approving change in location of C.P.R. station at Farm Point, from mileages 16.05 to 16.36, lot 240, R. 16, Tp. Hull.

19729—July 2—Amending Order No. 18161, dated Nov. 29, 1912, according to application of C.P.R., that words, "as lessee exercising the franchises of the Alberta Railway & Irrigation Company" in the recital of said Order, be struck out; and that plan "A.," filed under file No. 19574.1, showing location to be constructed by C.P.R., be substituted for plan approved under Order No. 18161.

19730—July 3—Granting leave to C.L.O. & W. Ry. to operate trains over crossing of Whitby, Port Perry & Lindsay Branch of G.T.R., in town of Whitby, for construction purposes only, for a period of six months from date of this Order, subject to and upon condition that crossing be protected by a watchman appointed by G.T.R., at expense of C.L.O. & W. Ry. (C.P.R.)

19731—July 3—Granting leave to Winnipeg, Selkirk & Lake Winnipeg Ry. to cross, for construction purposes only, until Oct. 31st, 1913, the Selkirk Branch of C.P.R., subject to and upon certain conditions.

19732—June 21—Approving revision in location of portion of C.P.R.'s constructed line, Shuswap sub-division, from station 1517-08.2 in S.E. ¼ Sec. 32-20-13, W. 6 M., at mileage 102.70; in southwesterly direction to station 1480, in N.E. ¼ Sec. 29-20-13, W. 6 M., at mileage 103.39, zero of said mileage being at Revelstoke, B.C.; 2, Revision in grade of line and highway crossings, as constructed, as shown on plan, be approved, and, 3, authorizing company to construct additional track (double track) across seven (7) highways, between mileages 96 to 131.55; 4, After diversion at mileage 102.92 is made and grade crossing constructed thereon in accordance with standard regulations of Board, company may close portion of present road allowance within limits of its right of way.

19733—July 2—Approving proposed change in location of C.P.R. station on N.E. ¼ Sec. 14-20-10, W. 6 M., at Salmon Arm, B.C.

19734—July 2—Authorizing C.P.R. to construct bridge No. 52.3 on Havelock sub-division, Ontario Division, over Salmon River, near Ardendale station, Ontario.

19735—July 2—Authorizing C.P.R. to construct ballast pit spur across road allowance between Section 12-34-25 and Section 7-34-24, W. 2 M., at mileage 54 from Wynyard, on Lanigan subdivision, Saskatchewan Division, by means of a grade crossing.

19736—July 2—Authorizing C.P.R. to operate bridges over Kaministiquia River and McKellar River, Fort William terminals, Ont.

19737—July 2—Authorizing C.P.R. to construct road diversion in N.W. ¼ Sec. 4-3-22, W. P. M., Man. After such diversion is made and grade crossing constructed in accordance with Regulations, company may close portion of present road allowance to be diverted between Secs. 9 and 4, Tp. 3, R. 22, W. P. M., portion to be closed being whole of road allowance extending along north boundary of N.W. ¼ of Sec. 4. And rescinding Order No. 15833, dated January 24th, 1912, made herein.

19738—June 30—Directing that G.T.P. Ry. adjust freight charges on sand received at Edmonton over company's railway, since June 21st, 1912, to basis of 2,600 lbs. per cubic yard; and that freight charges be collected on this basis until company's track scale is drained and corrected, or is removed and reinstalled, not later, in either case, than Nov. 1st, 1913.

19739—July 3—Authorizing C.P.R. to construct industrial spur to coal mines at Bienfait, Sask., by means of a grade crossing, across road allowance between Secs. 1 and 16-2-6, W. 2 M.

19740—July 3—Authorizing C.P.R. to operate trains over interlocking plant without their first being brought to a stop, where said company crosses Hull Electric Railway, in city of Ottawa.

19741—July 3—Authorizing C.L.O. & W. Ry. (C.P.R.) to construct its ballast pit spur, by means of a bridge, over and across G.T.R. at mileage 89.9 on its railway, in west ½ of Lot 9, Con. 1, Tp. Murray, Co. Northumberland, Ontario.

19742—July 3—Approving revised plan showing pedestrian subway proposed to be constructed by G.T.R. at Jacob's Ladder Stairway, town of Port Hope, Ont., filed as plan "A" under file No. 3675.5.

19743—July 2—Approving, subject to terms of agreement, proposed connection and junction of C.N.R. with N.T.R., Eastern Div., at St. Boniface, Manitoba.

19744—July 3—Directing that C.N.R. appoint caretaker at Hymers, Ont., whose duty it will be to keep waiting-room clean and heated, see that freight is properly housed and freight shed kept locked, and take charge of key of said freight shed, same to be kept at point convenient for persons coming for their goods between hours of 8 a.m. and 6 p.m.; station waiting room and outside of building to be painted, freight shed doors put in condition so that same can be locked, station platform repaired, and portable stock-loading chute be installed; caretaker be appointed and said work be completed by Aug. 15th, 1913.

19745—July 2—Approving (1) revised location portion of C.L.O. & W. Ry. (C.P.R.) from mileage 119 to mileage 119.66 (West Riding), Ont., and (2) location of said company's station on block of land lying to north of Park street, in Sub. Div. No. 8, Lot 17, town of Cobourg, Co. Northumberland (West Riding), Ont., at mileage 119.72 from Glen Tay.

19746—July 4—Authorizing C.P.R. to construct diversions of road allowances running north and south, and east and west, and bounding Secs. 19, 20, 29 and 30, Tp. 7, R. 27, W. 2 M., and to construct its Weyburn-Lethbridge Branch across diversion at mileage 94.28 from Weyburn, by means of grade crossing.

19747—July 4—Approving location C.N.Q.R. through Tps. Chilton and Lussier, Co. Montcalm, Que., mileages 36.52 to 57.49 from St. Jacques Jct.

19748—July 4—Approving location C.N.Q.R. through Tps. Chertsey and Rawdon, Co. Montcalm, Que., mileages 16.87 to 36.52 from St. Jacques Jct.

19749—June 28—Approving (1) Dominion Express Co.'s Schedules "B," C.R.C. No. 4345, to supersede C.R.C. No. 2583; "C," C.R.C. No. 4346, to supersede C.R.C. No. 2584; and "D," C.R.C. No. 4347, to supersede C.R.C. No. 2585, approved by Order No. 14418, dated July 19th, 1911. (2) C. N. Express Co.'s Schedule "B," C.R.C. No. 791, to supersede C.R.C. No. 725, approved by Order No. 14418, July 19, 1911. (3) Canadian Express Company's Schedules "B," C.R.C. No. 1514, to supersede C.R.C. No. 1364, and "C," C.R.C. No. 1515, to supersede C.R.C. No. 1365, approved by Order No. 14413, July 19, 1911; and (4) Great Northern Express Co.'s Schedules "A" and "B," C.R.C. No. 298, to supersede C.R.C. No. 270, approved by Order No. 14417, July 19th, 1911. Said tariffs to be published twice, consecutively, in the Canada Gazette.

19750—July 5—Approving proposed change in location C.P.R. station in N.E. ¼ Sec. 4-8-19, W. 2 M., at Khedive, Sask.

19751—July 4—Approving revised location Burrard Inlet Tunnel & Bridge Co.'s Railway from station high water mark, north shore Burrard Inlet, to station 174-88.7; and rescinding Order No. 505, dated June 13, 1905.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

▲—Denotes an item regarding work advertised in *The Canadian Engineer*.
+—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

RAILWAYS—STEAM AND ELECTRIC.

Moose Jaw, Sask.—On the completion of extensions being made by the Canadian Pacific Railway, this city will possess the third largest yards owned by the Canadian Pacific. Nearly 200 men are now engaged on the work of increasing the site of the terminal facilities, on which more than $100,000 is to be spent. In connection with the improvements, the trackage is being increased approximately 15 miles. The double track line from Swift Current into Moose Jaw is also nearing completion.

+—Ottawa, Ont.—The Morrisburg and Ottawa Electric Railway Company, it is reported, has awarded Mr. FRANK LEAMY the contract for the construction of the new road. Discussing construction matters, President Kilt stated he thought the road might be built for $15,000 per mile, exclusive of the cost of bridges and approaches, but he did not agree with the estimate made by some of the "insurgent" stockholders that $12,000 per mile was sufficient.

St. Catharines, Ont.—The Canadian Pacific Railway proposes to build an electric line from Hamilton, through St. Catharines, to the Niagara River. The city is asked to contribute one-half of the cost of a railway bridge across the old canal. As an alternative proposition, the C.P.R. is willing to use a bridge jointly with the Canadian Northern, which also intends to build through St. Catharines. In such a case the C.P.R. would pay one-third of the cost and expect the Canadian Northern and the city to bear similar proportions. The through line would be built through the northern section of St. Catharines, with a spur line to a new station to be erected at the market square. The city council looks favorably upon the proposition and will take up the new proposal with the Canadian Northern.

Toronto, Ont.—The Grand Trunk Railway management has placed an order for 75 of the most up-to-date locomotives. Fifty of them will be used on the Canadian lines while the other 25 will be used in the United States. These locomotives will be of the most modern type and the largest in the country. They will cost $25,000 each, so that the company will pay out $1,875,000 within the next year for motive power. Most of them will be built in the Montreal shops and some in Philadelphia.

+—Toronto, Ont.—The Canadian Northern Railway has awarded the following contracts in connection with the additions to the rolling stock: The contract for 7 consolidation locomotives to the CANADIAN LOCOMOTIVE COMPANY; 15 heavy ten-wheel locomotives to the MONTREAL LOCOMOTIVE WORKS; 6 first-class cars, 5 baggage cars and 50 box cars to the CANADIAN CAR AND FOUNDRY COMPANY; 2 combination cars to the PRESTON CAR AND COACH COMPANY; 5 second-class cars and 100 flat cars, 60,000 pounds' capacity, to the CROSSEN CAR COMPANY, and the contract for 170 Hart cars to the HART-OTIS CAR COMPANY.

Vancouver, B.C.—Foley, Welch & Stewart, of Vancouver, the contractors for double-tracking the Canadian Pacific Railway tunnel through the Selkirks, will require a great quantity of material and equipment in connection with the work. Manager A. C. Dennis announces that the cost of this alone will amount to about $500,000, and includes separate steam plants for both sides of the job.

Vancouver, B.C.—The Canadian Pacific Railway are to try the experiment of electrifying their branch line in Western Canada from Castlegar to Rossland, B.C., and operating trains between these two points by electricity instead of steam power, using 2,400 volts direct trolley system.

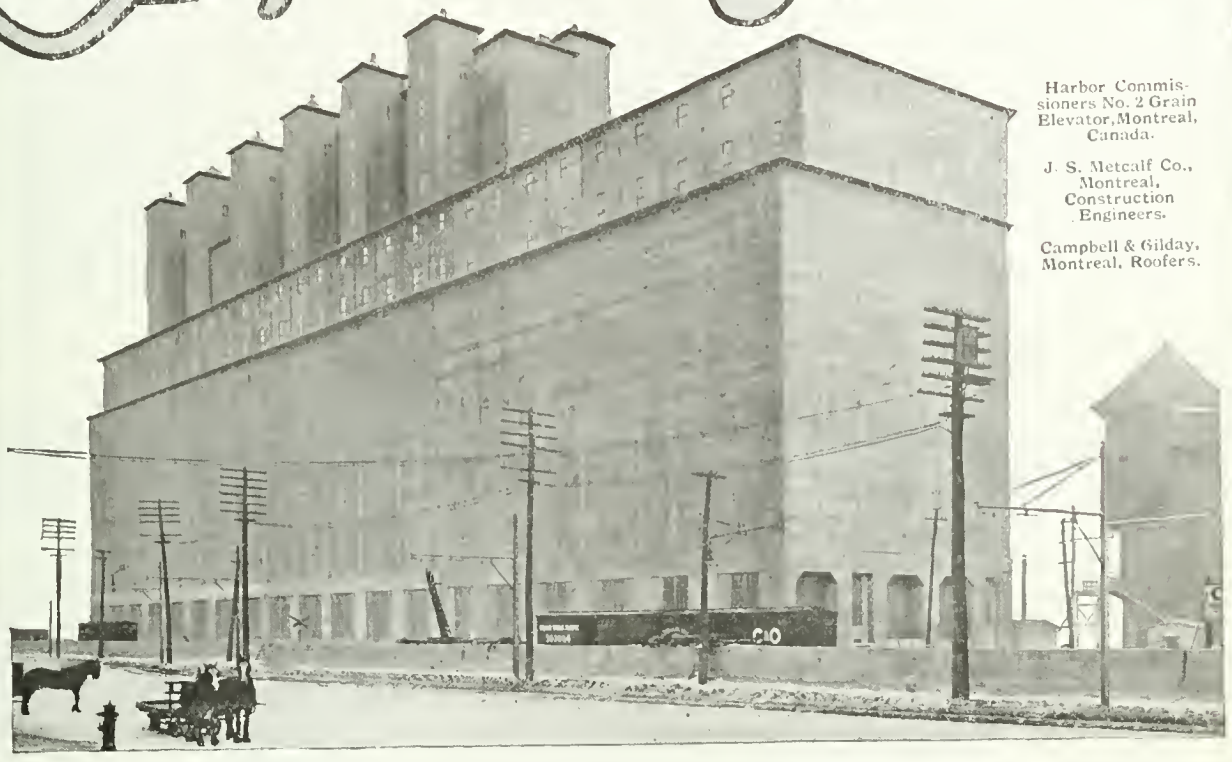
Vancouver, B.C.—The Canadian Pacific Railway is now starting to convert locomotives in the Vancouver-North Bend service into oil-burners, and it is expected that all the engines will be transformed by the end of the year.

Vancouver, B.C.—Tenders will shortly be called for the unfinished sixty-mile Kettle Valley line across the Hope Mountains, according to Mr. J. J. Warren, president of the company. The Kettle Valley Company will build, own and operate the section, but the Great Northern will contribute toward the cost and both will enjoy running rights. An early start on the work is assured.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—A number of by-laws to provide for paving are soon to be submitted to the ratepayers. They will be for extensions of pavements in places where the commissioners consider paving is an urgent necessity. The larger and most important will be a by-law providing for the paving of Nose Hill. It will be a general by-law and is planned as part of the policy of the health department to deliver garbage to the east end incinerator at the least possible expense.

Barrett Specification Roofs



Harbor Commissioners No. 2 Grain Elevator, Montreal, Canada.

J. S. Metcalf Co., Montreal, Construction Engineers.

Campbell & Gilday, Montreal, Roofers.

On the World's Largest Concrete Grain Elevator

As we have frequently pointed out, most of the large commercial buildings of the day are covered with a Barrett Specification type of roof.

For example, here is the great new grain elevator at Montreal. It is said to be the largest in the world, with a capacity of 2,600,000 bushels. It carries a Barrett Specification Roof 55,000 square feet in area.

The engineers chose this type of roof because it is the lowest-priced and most reliable roofing known.

Barrett Specification Roofs require no repairs or attention of any kind, they invariably last twenty years or more, and are fire-retardant.

Architects, engineers and owners of permanent buildings of all kinds should have a copy of the Barrett Specification on file.

A request will bring it by return mail.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification revised August 15th, 1911, using the materials specified and subject to the inspection requirement.

THE PATERSON MANUFACTURING COMPANY, LIMITED

Montreal Toronto Winnipeg Vancouver St. John, N.B. Halifax, N.S. Sydney, N.S.

+—Edmonton, Alta.—The city council has awarded Messrs. SMITH & KEITH the contract for the construction of two bridges, each 250 x 55 feet, of wood superstructure. The estimated cost is $27,194.

Halifax, N.S.—Tenders will be received up till the 28th of July, 1913, for the construction of bridges and culverts in the county of Annapolis. Plans and specifications may be obtained from the Department of Works and Mines, Halifax. E. H. Armstrong Commissioner.

+—Maplewood, Mo.—The DOLARWAY PAVING COMPANY have been awarded the contract for the construction of 1,750 square yards of their pavement there.

Ottawa, Ont.—City Engineer Currie is preparing an estimate as to the cost of placing every street in the city in good condition. And he is going at the matter in a very thorough manner. He has placed an engineer of the department at this work, and in addition has the ward foremen assisting. Each ward foreman has a map of his ward, and he is required to report on each street, giving the width of roadway construction and condition. The engineer in charge of the work is also taking various parts of the city and making reports. These reports will all be compared and amalgamated, and then City Engineer Currie will have accurate information on which to base the figures as to the cost of putting the various streets in shape. The report when ready will be a comprehensive one, but will not be out for a month yet.

Ottawa, Ont.—The counties of Lanark and Carleton have awarded MR. JAMES TODD, Burritt's Rapids, the contract for the construction of a bridge over the river between the two counties.

▲—Toronto, Ont.—Tenders will be received up till the 6th of August, 1913, for the construction of a reinforced culvert. Plans and specifications may be obtained from Frank Barber, County Engineer.

▲—Toronto, Ont.—Tenders will be received up till the 6th of August, 1913, for the construction of a bridge. Plans and specifications may be obtained from Frank Barber, County Engineer.

Welland, Ont.—Tenders will be received up till the 28th of July, 1913, for the construction of three concrete bridges. Plans and specifications may be obtained from George Ross, county engineer, and Robt. Cooper, county clerk.

▲—Welland, Ont.—Tenders will be received up till the 4th of August for the construction of sewers. Plans and specifications may be obtained from *The Canadian Engineer*, 62 Church Street, Toronto, and James Hughes, Chairman Sewerage Committee.

LIGHT, HEAT AND POWER.

Brantford, Ont.—Tenders will be received up till the 30th of July, 1913, for the construction of a substation building. Specifications may be obtained from Brantford Hydro-Electric System, Brantford, Ont.

Edmonton, Alta.—The EDMONTON CONSTRUCTION COMPANY and Messrs. HULBERT & WILSON have been awarded the contracts for the extension to the telephone system. The prices were $33,500 and $18,666, respectively.

London, Ont.—The report of Mr. A. Eastman, manager of the Essex and Lake Shore Railway on the estimated amount of earnings and operating expenses of the London and Port Stanley Railway if electrified, has been made public. The report is disappointing, inasmuch as it shows clearly the unfeasibility of the scheme, and that the road could not be run by electricity except at a loss to the city.

Ottawa, Ont.—Tenders will be received up till the 14th of August, 1913, for the supplying of 47,000 feet of underground lead cavend cables and 14 induction regulators. Specifications may be obtained from J. E. Brown, electrical superintendent.

+—Regina, Sask.—The City Commissioners have awarded Messrs. BRUCE, PEEBLES & COMPANY, LIMITED, Edinburgh, through their Eastern Canadian agents the contract for supplying a 1,200 K.W. motor generator.

Winnipeg, Man.—Tenders will be received up till the 31st of July for supplying 25,000 lbs. of weatherproof insulated copper wire. Plans and specifications may be obtained from the Board of Control. M. Peterson, secretary.

GARBAGE, SEWAGE AND WATER.

▲—Bassano, Alta.—Tenders will be received up till the 15th of August, 1913, for the construction of a sewage disposal works. Plans and specifications may be obtained from the John Galt Engineering Co., Ltd., consulting engineers and Geo. B. R. Bond, secretary-treasurer.

Calgary, Alta.—City Engineer Craig has completed the estimates of cost and the by-law is now ready to be submitted to the council. The by-law provides for a trunk sewer to cost $45,500 and laterals and accessories to cost a total of $32,400 more. It is the intention of the commissioners to get the work under way as soon as circumstances will permit.

+—Edmonton, Alta.—The city engineer, A. J. Latornel, reports to the commissioners showing an analysis of the tenders on water and sewer contracts for Riverside and Glenora. These tenders are recommended to be accepted:—For sewers, contracts 6 and 7: C. L. DEVALL, for contract 6, $42,046; for contract 7, $22,215.25. For water—Contract 6, C. STANGER, $11,489.20; contract 7, C. L. DEVALL, $4,611.50. The tenders submitted both for the water and the sewer contracts were: Water main, Glenora contract 6—W. Graham, $12,130.95; C. L. DeVall, $11,732.25; G. Stanger, $11,489.20 and Philip Agrois, $14,100.40. Water main, Glenora contract 7—W. Graham, $4,998.50; C. L. DeVall, $4,611.50; G. Stanger, $4,812, and Philip Agrois, $6,158.75. Sewer, Glenora contract 6—Hulbert & Wilson, $58,221.60, and C. L. DeVall, $42,046. Sewer, Riverview, contract 7—A. J. McGarry, $34,158.10— Hulbert & Wilson, $25,287.85; C. L. DeVall, $22,215.25, and Benson and Mills, $24,624.75.

+—Montreal, Que.—The Board of Control has awarded the ALLIS-CHALMERS COMPANY the contract for supplying an electric-driven pump, of six million gallons capacity of the high level reservoir. The Canada Boving Company and the Escher, Wyss Co. also tendered.

+—Montreal, Que.—The Board of Control has awarded the WICKS COMPANY the contract for supplying two steam boilers for the low level station. The tender price is $16,000, which was the lowest.

Montreal, Que.—The long-expected report on the filtration plant prepared by F. N. Barbour, of Boston; J. A. Jameson and P. W. St. George, of Montreal, was handed to the Board of Control recently. The report deals with the nature of the ground, etc., upon which the filtration plant at the wheel-house is being constructed. The report bears out the contention of Mr. G. Janin, chief engineer of the city; T. Lesage, superintendent of the waterworks, and of Messrs. Hering and Fuller, filtration experts, of New York, that the site of the plant is satisfactory, and that it is capable of bearing much heavier loads than those called for by the city's specifications. Upon the strength of this new report the Board of Control will decide whether to allow the contractor to complete the work or whether the city will carry out the contract itself.

Oshawa, Ont.—Tenders will likely be called for later in the season for laying of new intake pipe. A pressure mechanical filtration plant will likely be installed in 1914, if the water becomes as turbid next winter as it did last winter.

▲—Victoria, B.C.—Tenders will be received up till the 31st of July, 1913, for the fabrication and laying of about 10¼ miles of 36-in. riveted steel pipe and appurtenances on the line of the Sooke Water Supply. Plans and specifications may be obtained from C. H. Rust, Water Commissioner.

▲—Victoria, B.C.—Tenders will be received up till the 31st of July, 1913, for the laying of about 27½ miles of reinforced concrete pipe and appurtenances on the line of the Sooke Water Supply gravity conduit. Plans and specifications may be obtained from the Sooke Water Supply office, and C. H. Rust, Water Commissioner.

Welland, Ont.—The town will call for tenders for the construction of sewers shortly. D. T. Black, town engineer.

INDUSTRIAL WORKS.

+—Bruce Mines, Ont.—The Dominion Government has awarded the SOO DREDGING AND CONSTRUCTION COMPANY the contract for dredging. The contract price is $8,832.

+—Calgary, Alta.—The JAMES G. CORCORAN COMPANY, Calgary, have been awarded the contract for the con-

48 in CONTINUOUS STAVE LINE.

Manufacturer of

Galvanized Wire Machine Banded

WOOD STAVE PIPE

CONTINUOUS STAVE PIPE

RESERVOIR TANKS

For City and Town Water Systems, Fire Protection, Power Plants, Hydraulic Mining, Irrigation, etc.

Full particulars and estimates furnished.

PACIFIC COAST PIPE COMPANY, LTD.

Factory : 1551 Granville Street, VANCOUVER, B.C. P.O. Box 365.

MANNESMANN STEEL TUBES

FOR WATERWORKS HYDRO-ELECTRIC AND GAS MAINS

WELDLESS TUBES up to 12 inches diameter, in lengths up to 40 feet.

Laying Mannesmann Pipes under water in Netherlands

LAP-WELDED TUBES from 12 inches up to the largest diameters.

MANNESMANN TUBE COMPANY, LIMITED

51 VICTORIA SQUARE, MONTREAL

struction of a twelve-inch pipe line from Carlish, Kansas to Carlton, Mo., a distance of 100 miles.

Fort William, Ont.—Extensions and improvements to the Kaministiquia Power Company's plant, which will mean an outlay of approximately $1,000,000 will be commenced in the very near future, according to Mr. R. S. Kelsch, consulting engineer for Hosmer, Holt and Thompson, of Montreal, principal owners of the plant. It is the intention to instal a third big aqueduct from the intake pipe to the power house, a distance of little over a mile.

Halifax, N.S.—Tenders will be received up till the 1st of August, 1913, for dredging required at Cheticamp, Little Lorraine, Petit de Grat, Whycocomagh and Port Mulgrave, Nova Scotia. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Kerrisdale, B.C.—Tenders will be received up till the 28th of July, 1913, for supplying fire apparatus. Specifications may be obtained from G. G. Heighway.

Kerrisdale, B.C.—Tenders will be received up till the 28th of July, 1913, for the construction of an incinerator. Plans and specifications may be obtained from G. G. Heighway, C.M.C.

+—Killarney, Ont.—The Dominion Government has awarded the C. S. BOONE DREDGING COMPANY the contract for dredging. The contract price is $8,000.

London, Ont.—City Engineer Ashplant has submitted his report to the Board of Works on the breakwater question. In reviewing the question the engineer stated that in the past fifteen years $21,178 had been spent on the breakwater for piling, planking and general filling. None of this work had been of a permanent character and he recommended a permanenet construction paid for out of debentures, as the saner and better policy. He reviewed the previous reports on various types of construction and recommended a reinforced embankment, faced with concrete, as the most effective form of construction. The estimated cost of this would be $12.40 per foot, and would provide for the required gravel and earth filling (40,000 yards), the reinforced concrete facing and a pipe rail fence for the protection of the top of the bank. With an additional 10 per cent. for contingencies the cost would amount to $22,139.

Ottawa, Ont.—Tenders will be received up till the 28th of August, 1913, for the construction of a single-screw steel steamer. Plans and specifications may be obtained from the Department of Marine and Fisheries, Ottawa. Alex. Johnson, Deputy Minister.

+—Ottawa, Ont.—The contract for a modern power lifeboat, it is expected, will be awarded to V. M. DAFOE, of Vancouver, the price mentioned being in the neighborhood of $10,000. The arrangement is in pursuance of the policy of the Administration of having all vessels for the Government service built in Canada. The new vessel will be stationed at Claquot, on Vancouver Island, and will be the third of the sort in Canada. They are 36 feet, ocean-going vessels, unsinkable and self-righting. The new boat is to be built in accordance with the specifications of the United States authorities.

+—Ottawa, Ont.—The Dominion Government has awarded the DOMINION DREDGING COMPANY, Ottawa, the contract for the construction of the first section of the enlarged Welland Canal. The firm offered to do the work for $3,500,000. This was the lowest tender. It provides for the construction of the first few miles of the canal from the Lake Ontario end. Tenders for other sections of the canal, which is to have a depth of 34 feet, will be called shortly. It will, when completed, allow the largest lake boats to reach the St. Lawrence with full grain cargo from the west.

Ottawa, Ont.—The Board of Control have passed local improvements amounting to $250,000.

Regina, Sask.—The city is calling for tenders for the construction of 500,000 square feet of concrete sidewalks, and City Engineer McArthur is calling for tenders for equipment required for street cleaning and road grading.

+—St. Andrew's, N.S.—The Dominion Government has awarded the MARITIME CONSTRUCTION COMPANY the contract for dredging. The contract price is $7,03[illegible].

The Pas, Man.—Tenders will be received up till the 1st of August, 1913, for the constructing and equipping wireless telegraph operating house. Plans and specifications may be obtained from Chief Engineer Hudson Bay Railway, Winnipeg, and the Department of Railways and Canals. L. K Jones, secretary.

▲—Toronto, Ont.—Tenders will be received up till the 5th of August, 1913, for painting several bridges. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

▲—Toronto, Ont.—Tenders will be received up till the 25th of August, 1913, for the construction of a sea wall, breakwater, ship channel and retaining walls. Plans and specifications may be obtained from the District Engineer and the Harbor Commissioners, Toronto; H. J. Lamb, Windsor; J. L. Michaud, Montreal; and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Toronto, Ont.—The Spanish River Pulp and Paper Company, the Lake Superior Company and the Ontario Pulp and Paper Company have merged. The Spanish River Pulp and Paper Mills, Limited, is one of the largest manufacturing concerns in the Dominion. Its pulp limits, coursed by the Spanish, Vermilion and Onaping Rivers, cover an estimated area of 6,000 square miles, and possesses a twenty-one-year agreement with the Ontario Government. The company's mill and plant are at Espanola and Sturgeon Falls. The concern owns its water and electric power plant. The shareholders will be asked for permission for the directors to approach the Lieutenant with a view to obtaining supplementary letters patent increasing the capital stock of the company to $20,000,000.

▲—Toronto, Ont.—Tenders will be received up till the 5th of August, 1913, for the equipment of the civic abattoir. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Mayor.

+—Vancouver, B.C.—The Dominion Government has awarded the VANCOUVER SHIP YARD LIMITED, the contract for the construction of three gasoline launches.

Vancouver, B.C.—As evidence of the work carried on by the Canadian Pacific Railway in the way of assisting firms to locate in the west, the industrial branch of the natural resources department of the company reports that, up to the end of June, the department had been instrumental in establishing 56 retail businesses, 31 wholesale houses, and 89 manufacturing plants in Western Canada.

+—Victoria, B.C.—The city council has awarded the following contracts for supplies:—F. H. FOLSAM, the contract for supplying 100 cedar poles; to Messrs. NEPAGE, McKENNY & COMPANY the contract for installation cables, junction boxes, etc., and installing arc lighting on Dallas Road; to Messrs. HUTCHINSON BROS. the contract for supplying cluster light globes.

+—Winnipeg, Man.—The School Board has awarded JAMES BALLANTYNE & COMPANY the contract for installing a heating and ventilating system in the Mackray school. The contract price is $19,557.

MISCELLANEOUS.

+—Calgary, Alta.—The Government has awarded Mr. F. L. DAVIS the contract for the rebuilding of a boarding school on the Blackfoot Indian reserve. The contract price is $50,990.

Calgary, Alta.—The Crystal Ice Company, manufacturers of artificial ice, will erect a plant in this city. The estimated cost is $200,000.

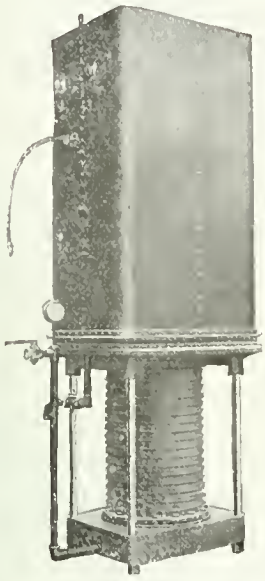
Calgary, Alta.—The Canada Malting Company will locate a machine shop in this city. The cost will be $10,000.

▲—Cobalt, Ont.—Tenders will be received up till the 15th of August, 1913, for the erection of a three-story concrete and municipal building. Plans and specifications may be obtained from R. L. O'Gorman, town clerk.

+—Duncan, B.C.—The Dominion Government has awarded MESSRS. ROURKE, McDONALD & MONCRIEF, the contract for the erection of a public building. The contract price is $38,463.

+—Edmonton, Alta.—The directors of the Exhibition have awarded the DUNLOP-JOHNSON CONSTRUCTION COMPANY the contract for the construction of the stock pavilion.

The Pistonless Hydraulic Press



40-Ton Steam Heated Press

Gives unlimited pressures without ram, pumps, motive power, cup leathers, leakage, special foundations or technical difficulties.

The low pressure existing in the ordinary water main, acting upon the large area of an armoured collapsible cylinder in the Pistonless Press, gives pressures which in the Ram Press can only be obtained through high pressures created by pumps. Thus the Pistonless Press eliminates the expense of complex machinery, foundations and skilled attendance, as well as the friction losses in the Ram Press.

The initial cost of the Pistonless Press is less than one-half that of a Ram Press plant of equal capacity, and the upkeep and running costs are negligible. No skilled attention is required—a boy can operate it.

Write for full particulars, stating purpose for which you require a Press, to

JOHN MILLEN & SON, LIMITED

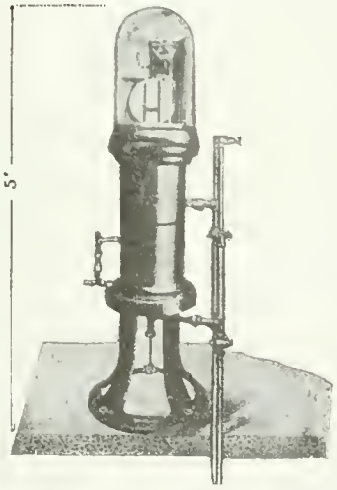
Simplex Water Meter

Type 'G' Register

adaptable and furnished with either Venturi tubes or Pitot tubes, and now fully developed and successfully tested for Triangular Notch or Rectangular Weirs.

Hot or Cold Water



Actuating power, simple shaped float in mercury.
Greatest range of flow with minimum friction through Venturi tube.
No cams—uniform graduations.
One eight-day marine clock.
Rectangular chart—daily or weekly. Total flow five dial register—glass dome or metal dome with glass doors, if desired.
Chart can be averaged with ordinary planimeter.
Indicating dial may be graduated in gallons, cubic feet, pounds or horse power.

Particulars, diagrams, tests and other data upon request.

Write for catalogs

The **SIMPLEX VALVE & METER** Company

112 North Broad Street, PHILADELPHIA

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction ot the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

Sterilization Co.

Union Building, Clinton Street

NEWARK, N. J.

Also engineers for the electrolytic treatment of water.

+—**Edmonton, Alta.**—The Board of Commissioners have awarded MESSRS. NESBITT & MILLER the contract for the construction of a fire hall. The contract price is $11,942.

+—**Elmira, Ont.**—The Dominion Government has awarded Mr. E. A. BLEAKNEY the contract for the erection of a public building. The contract price is $35,000.

+—**Hartford, Conn.**—The MACARTHUR CONCRETE PILE AND FOUNDATION COMPANY, New York, has been awarded the contract for the complete foundation for the new Hartford City Gas Light Company retort buildings.

Indian Head, Sask.—Tenders will be received up till the 28th of July, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

+—**Madoc, Ont.**—The Dominion Government has awarded Mr. L. E. ALLEN, Belleville, the contract for the erection of a drill hall, the contract price of $16,800 being the lowest.

+—**Maple Creek, Sask.**—The Dominion Government has awarded NAVIN BROTHERS, of Moose Jaw, the contract for the erection of a drill hall. The contract price is $27,313.

+—**Medicine Hat, Alta.**—The Medicine Hat Golf and Country Club have awarded Messrs. SCANLON & HALL the contract for the erection of a club house. The contract price is $12,000.

Ottawa, Ont.—Rapid progress is being made in equipping the militia with drill halls. Nineteen are now under contract, tenders are in and under consideration for eight more, and tenders have been called for twenty-five additional. This makes a total of fifty-two centres which are being supplied at the present moment with accommodation.

+—**Preston, Ont.**—The Dominion Government has awarded Mr. GEO. E. PROCTOR the contract for the erection of a public building. The contract price is $44,861.

+—**Prince Albert, Sask.**—The Bank of Ottawa has awarded MR. A. P. ANDERSON the contract for the erection of an addition to the present building. The contract price is $40,000.

Regina, Sask.—The Canadian Pacific Railway will build a large hotel at Long Lake, a popular pleasure resort.

Regina, Sask.—Tenders will be received up till the 31st of July, 1913, for the erection of an isolation hospital. Plans and specifications may be obtained from L. A. Thornton, City Commissioner.

Renfrew, Ont.—Tenders will be received up till the 8th of August, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy-Minister.

+—**Saskatoon, Sask.**—Dr. G. E. Holmes has awarded the FRID-LEWIS CONSTRUCTION COMPANY the contract for the erection of a six-story block. The contract price is $250,000.

+—**Shelburne, Ont.**—The Dominion Government has awarded Messrs. ALEX GREEN and H. N. CAMPBELL the contract for the erection of a public building. The contract price is $29,707.

Sudbury, Ont.—Tenders will be received up till the 6th of August, 1913, for the erection of a public building. Plans and specifications may be obtained from Thos. Hastings, Toronto, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

St. John, N.B.—The municipal council will erect a hospital for consumptives. The estimated cost is $46,900.

+—**The Pas, Man.**—The Dominion Government has awarded Messrs. SNYDER BROS. the contract for the erection of an Indian boarding school and hospital. The contract price is $76,578.

Toronto, Ont.—The United Typewriter Company will erect a new ten-story building. The estimated cost is $150,000.

+—**Toronto, Ont.**—The Government has awarded Messrs. MITCHELL & SON the contract for the erection of postal station "G." The contract price is $124,000.

+—**Toronto, Ont.**—The Canadian Pacific Railway has awarded the JOHN HAYMAN AND SON COMPANY the contract for the erection of a building to be an addition to the coach repair department. The contract price is $26,000.

+—**Vancouver, B.C.**—The Credit Foncier has awarded H. L. STEVENS & COMPANY the contract for their ten-story building. The building is to be of reinforced concrete construction.

+—**Vancouver B.C.**—The city council have awarded Mr. FRANK J. PALO the contract for the erection of the proposed police station.

+—**Vancouver, B.C.**—The Salvation Army has awarded MR. J. W. SPENCER the contract for two new buildings. The contract prices are $20,000 and $30,000 respectively.

+—**Victoria, B.C.**—The city has awarded Messrs. HANSON & JOHNSTON the contract for the erection of Ridgedale School, in the Matsqui district.

+—**Winnipeg, Man.**—Messrs. G. F. and J. Galt have awarded the J. A. GIRVIN COMPANY the contract for the interior alterations of their warehouse. The estimated cost is $25,000.

+—**Winnipeg, Man.**—The Government has awarded MESSRS. CARTER, HALL AND ALDINGER the contract for additions to the Selkirk Asylum. The contract price is $64,000.

MONTREAL MARKET REPORT

If the iron and steel trade is not more cheerful in other parts of the Dominion than it is in Montreal, there will not be many good things said of it at the present time. No doubt the local dullness is largely due to the conditions on the other side of the international boundary. In addition to this, however, there is some easing down in Canadian industrial activity and this is naturally reflected in the iron and steel trade.

Advices from the United States are doing their best, as it were, to look cheerful. From Chicago comes the news that the pig iron market is showing increased strength, owing to a falling off in production of merchant furnaces. This is not the best reason for strength, but in the absence of a still better one, it will have to contribute its cheer. As an American critic says, with the limitations imposed by money conditions, iron and steel works are dealing more and more with the country's up-keep requirements. It is the unknown factor, the time and the extent of the release of funds for new enterprises which account for the diverse views entertained in the steel trade as to its course in the late months in the year.

In the United States, it is claimed that supplies of steel are nearing exhaustion at a number of points. This will, of course, contribute to firmness, but it will not make volume of business, inasmuch as if the mills were all operating they would not be able to market their output and the price would have to decline. Conditions in the steel market, however, have been making a better showing right along than in the pig iron market and, notwithstanding all the unfavorable occurrences, the United States Steel Corporation has been making a fair profit and, according to all accounts, will be able to show its dividends and a balance. Nevertheless, it is acknowledged that the incoming business is exceedingly small. Some statistics published recently gave this incoming business in daily rate, as follows:—

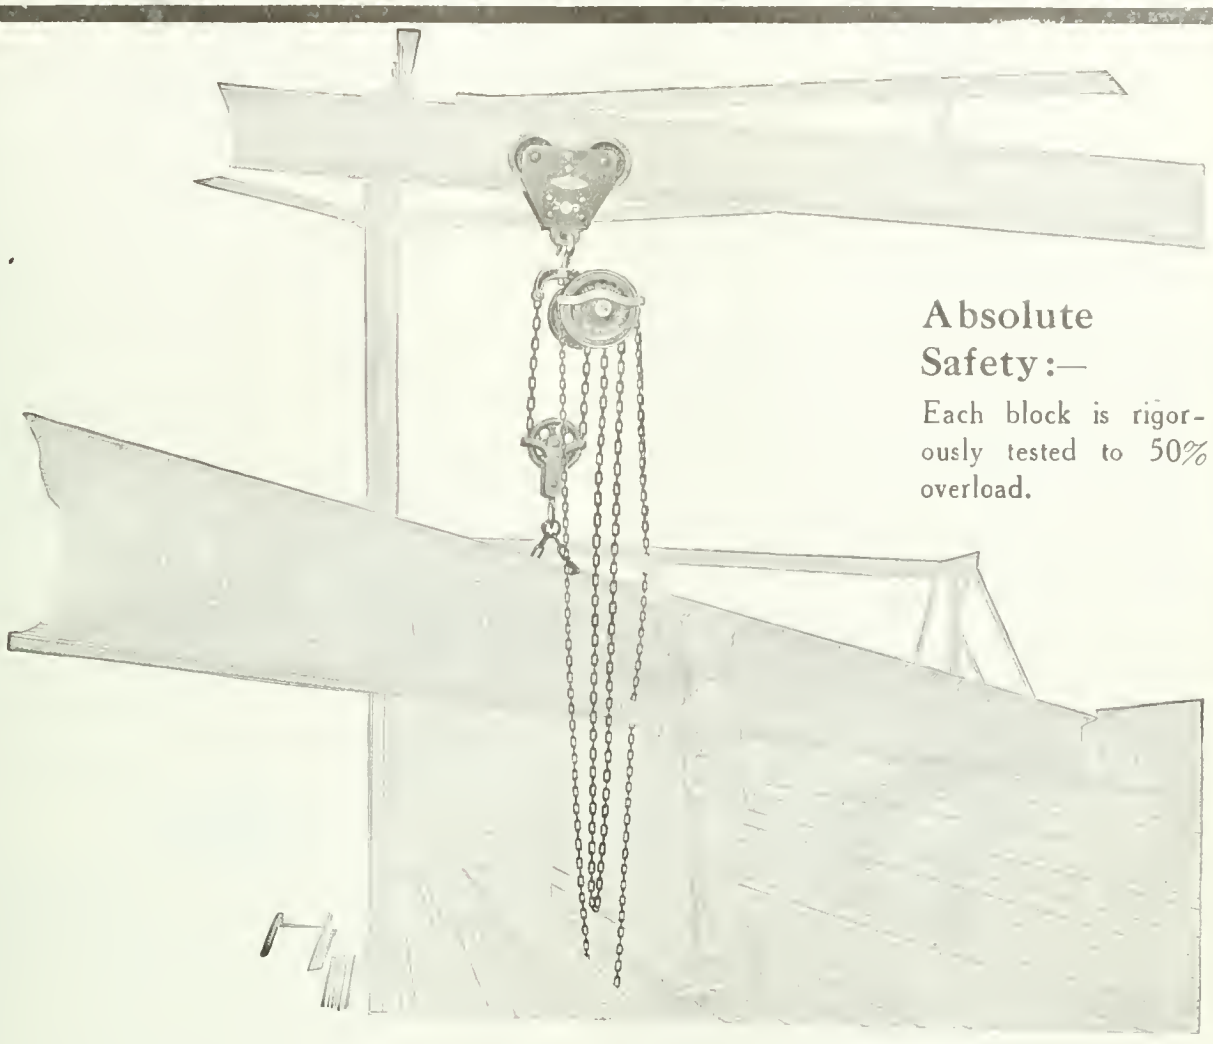
1912, October	...75,000 tons	1913, January	...40,500 tons
" November	53,000 "	" February	..38,000 "
" December	46,000 "	" March	.....37,000 "
		" April	.....26,000 "
		" May	.....20,800 "
		" June	.....23,000 "

The above related to the Steel Corporation and doubtless is as favorable a showing as the other companies are making. Since the middle of June, it is thought that operations have fallen off at least 5 per cent.

It is hard to say to what extent the recent strike of iron moulders in the city of Montreal may have interfered with the iron trade. It is understood that most of the men have gone back to work again. The men insisted on a nine-hour day and the employers refused to treat with them, claiming that they had only made a contract with them a year ago. It is doubtful if the iron and steel trade here is more optimistic than previously, as is reported to be the case in the United States, and it may even be that the contrary is the case.

A demand will shortly spring up for shipment before the close of navigation, but it is doubtful if this demand will bear a very cheering comparison with the customary fall demand. Meantime dealers generally quote prices the same as a week ago.

THE TRIPLEX BLOCK



Absolute Safety:—

Each block is rigorously tested to 50% overload.

STOP REHANDLING LOADS.

LIFT your load, move your load and lower your load by the same device, merge the three operations into one. You will then reduce rehandling; you will then save labor and time. That is the principle of the derrick.

Apply that principle in your shop and yard. Apply it by means of a Triplex Block on an overhead track. The trolley is light running, the track is level and no obstructions are in the way.

Triplex blocks are steel; steel from load-hook to I-beam. One worker alone handles ten tons, 20,000 pounds, with absolute safety; he can lift, transport and adjust steel plate, for instance, as he would handle a sheet cork. Weight or fear no longer limits his output.

Procure your copy of the new Book of Hoists now. There are concise tables, data, suggestions and photographs with action. Post yourself on the new handling practice.

TRIPLEX BLOCKS: 16 Sizes: One-quarter of a ton to forty tons. 300 Active Stocks all over the United States and Canada.

Also Duplex Blocks, Differential Blocks and Electric Hoists.

The Canadian Fairbanks-Morse Company, Limited

YALE PRODUCTS

MONTREAL TORONTO CALGARY ST. JOHN WINNIPEG VANCOUVER OTTAWA SASKATOON VICTORIA

TENDERS CALLED FOR

TENDERS FOR EQUIPMENT OF MUNICIPAL ABATTOIR AND RENDERING BUILDING NOW BEING ERECTED AT THE FOOT OF TECUMSEH STREET, TORONTO.

Separate Tenders for the several trades mentioned below in connection with the above buildings will be received by registered post only, addressed to the undersigned, up till noon on

TUESDAY, 5th AUGUST, 1913.

1. Machinery for Killing Departments, Pens, Iron Fencing, etc., Tanks, and Rendering Machinery.
2. Ice Machine and Motor, with all Piping, Condenser, and Foundations.
3. Insulation of Chill Room—floors and walls.
4. Electric Wiring, Fixtures, etc.
5. Steam Heating for Offices and Men's Rooms.
6. Cattle Chute, Connecting Bridge, Conduct, Catch Basin, Chimney, Elevators, Chill Room, Drip Pans.
7. Boiler Room Equipment, including Boilers, Heater, all Piping, Fittings, and Pumps.
8. General Painting of Buildings, Iron Work, Machinery, Pens, Fences, etc.

Plans and specifications may be seen and forms of tender and all information obtained at the office of Messrs. William R. Perrin and Company, 530 King Street East, Toronto, and No. 200 Old Colony Building, corner Dearborn and Van Buren Streets, Chicago, Ill.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by City By-law must be strictly complied with or tenders will not be entertained, and all tenders are to be subject to the condition that the work will be finished by April 1st, 1914.

Parties tendering shall submit with their tender the names of two personal sureties or the bond of a Guarantee Company.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman Board of Control.

TENDERS FOR THE CONSTRUCTION OF SEWERS.

Sealed tenders will be received by Mr. C. M. Webber, Town Clerk, Welland, Ontario, up to 5 p.m. on Monday, 4th August, 1913, for the construction of Separate Sewers on the following streets:—

Maple Avenue; William Street; Oakland Avenue; Asher Street; River Road; Duncan Street; Cady Street; John Street.

Specifications and tender forms may be had at Engineer's Office, Welland. Plans and specifications may also be seen at the office of *The Canadian Engineer*, 62 Church Street, Toronto, on or after 25th instant.

A marked cheque for 10 per cent. of the amount of the tender must accompany each tender, or an acceptable bidder's bond of same value will be accepted.

The lowest or any tender not necessarily accepted. The tenders may be awarded separate or in bulk.

JAMES HUGHES,
Chairman Sewerage Committee.

Welland, July 22nd, 1913.

TENDERS FOR BRIDGE CONSTRUCTION.

Sealed Tenders plainly marked as to contents will be received by the undersigned up to NOON of WEDNESDAY, AUGUST 6th, 1913, for the construction of a reinforced concrete beam bridge on Yonge Street, just north of Aurora, in the County of York.

Plans and specifications and all necessary information may be seen at the office of the undersigned, 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
County Engineer.

Toronto, July 22nd, 1913.

NOTICE TO CONTRACTORS

Sealed proposals will be received at the offices of the Water Commissioners, City Hall, until 12 noon, July 31st, 1913, for the fabrication and laying of about 10¼ miles of 36-in. riveted steel pipe and appurtenances on the line of the Sooke Water Supply pressure conduit, and in accordance with the requirements of the general specifications prepared by Wynn Meredith, Consulting Engineer for such construction, pursuant to the provisions of By-law No. 814.

Plans and Specifications can be seen, and Forms of Tender obtained at the Sooke Water Supply Office, 1414 Douglas Street, Victoria, B.C.

The lowest or any tender not necessarily accepted.

C. H. RUST,
Water Commissioner.

Victoria, B.C., June 27th, 1913.

Sealed tenders addressed to the undersigned and endorsed "Tender for Toronto Harbour Works," will be received at this office until 4 p.m., on Monday, August 25th, 1913, for the construction of a Sea Wall, Breakwater, Ship Channel and Retaining Walls at the City of Toronto, in the County of York, Province of Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this department and at the offices of J. S. Sing, District Engineer, Confederation Life Building, Toronto, Ont.; Harbor Commissioner's Office, 76 Adelaide Street West, Toronto; H. J. Lamb, Esq., District Engineer, Windsor, Ont.; and J. L. Michaud, Esq., District Engineer, Post Office, Montreal, Que.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to five per cent. (5 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, July 12, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—44297.

For further Tenders see page 86.

An Invitation

We cordially invite all engineers and architects to correspond with us regarding fireproofing when designing new structures. Our knowledge of fire protection and the matters that govern insurance rating is very thorough and highly specialized. Without charge this knowledge is at the service of engineers and architects so that when their structure is complete we will be able to obtain for them the very lowest possible insurance rate.

136 St. James Street · Montreal

Cost of pipe = 20% cost of work
Saving by using poor pipe = 20%
Saving on total cost = 4%

IS IT WORTH WHILE?

If the sewer is to cost $10,000, for instance, MIMICO pipe would likely not cost more than $2,000, probably considerably less. Not more than $400 could be saved on this pipe cost by purchasing a poor grade of pipe. You would then have a poor sewer costing $9,600, when for $10,000 you might have had the very best sewer possible to build. Is it worth while to buy poor pipe? No! Then buy Mimico Brand and put an end to sewer troubles.

NOW READY
FOURTH EDITION, Revised and Enlarged

GEBHARDT—**Steam Power Plant Engineering**

By G. F. Gebhardt, Professor of Mechanical Engineering, Armour Institute of Technology. 8vo, xvi + 966 pages, 605 figures. Cloth, $4.00 net.

The development of Steam Power Plants has been so rapid during the past three years that it has become necessary to re-write this book. Over three hundred new illustrations have been added, and the entire text has been reset.

Note the reduction in price from $6.00 net to $4.00 net.

PEABODY—**Computations for Marine Engines**

By Professor Cecil H. Peabody, Massachusetts Institute of Technology. 8vo, iv + 209 pages, 52 figures. Cloth, $2.50 net.

This book gives the methods of computing the proper size and strength of the parts of a marine engine, similar to those in good practice, with special attention to instruction, and perhaps carried to a somewhat greater degree of refinement.

PEABODY—**Propellers**

By Professor Cecil H. Peabody, Massachusetts Institute of Technology. 8vo, iii + 132 pages, 29 figures. Cloth, $1.25 net.

Gives a reliable and convenient method of designing propellors, based on model experiments, and free from all theoretical intricacies and uncertainties.

KING—**Steam Engineering.** A Text-book

By William R. King, U.S.N., Retired. Principal of the Baltimore Polytechnic Institute. 8vo, vii + 450 pages, 177 figures. Cloth, $4.00 net.

Presents concisely the principles and constructive details of the make-up of a steam-power plant, together with such calculations as are necessary for a practical knowledge of steam engineering.

TENDERS CALLED FOR

TENDERS FOR PAINTING BRIDGES.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on **Tuesday, August 5th, 1913,** for painting North Glen Road Bridge over Rosedale Ravine, St. Clair Avenue (Moore Park), over Vale of Avoca, and Wallace Avenue Bridge (footbridge over C.P.R. and G.T.R tracks).

Specification and tender form may be obtained upon application at the office of the Railway and Bridge Section, Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relative to tendering as prescribed by City By-law must be strictly complied with or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor).
Chairman, Board of Control.

City Hall, Toronto,
July 15th, 1913.

TOWN OF BASSANO, ALBERTA.

SEWAGE DISPOSAL WORKS.

Sealed tenders, addressed to the undersigned, will be received up till 18 o'clock on Friday, 15th August, 1913, for all labor and materials (except filter distributors) necessary for the construction of sewage disposal works, consisting of tank and filter and relative works near the town of Bassano.

Tenders must be accompanied by an accepted cheque for five per cent. of the amount of the tender, or alternatively by the bond of an approved guarantee company.

Plans and specifications and other information may be obtained at the offices of the Consulting Engineers at Winnipeg and Calgary, on deposit of $25, which will be returned to bona fide tenderers on return of the plans.

The corporation do not bind themselves to accept the lowest or any tender.

GEO. B. R. BOND,
Secretary-treasurer, Bassano, Alta.

July 1913.
The John Galt Engineering Co., Ltd.,
Consulting Engineers.

TENDERS.

Will be received by the undersigned up to Friday, August 15th, 1913, for the erection of a three-story concrete and brick municipal building for the town of Cobalt, approximately 43 feet x 100 feet, according to plans and specifications prepared by Messrs. Angus and Angus, architects, North Bay.

Contractors are required to enclose a marked cheque along with each tender for 5 per cent. of the amount of same, the lowest or any tender not being necessarily accepted.

Work to commence immediately on award of contract.

Plans and specifications may be seen at the office of the architect or at the office of the undersigned.

R. L. O'GORMAN,
Town Clerk.

Cobalt, Ont.

TOWN OF CARLYLE, SASKATCHEWAN.

WATERWORKS AND ELECTRIC LIGHTING.

Sealed tenders, addressed to the undersigned, will be received up till 18 o'clock on Friday, 1st August, 1913, for the following contracts:—

1.—Construction of brick power house and concrete reservoir, and laying approximately 800 lineal feet of pipe in trenches, and relative works.
2.—Supply of Air-lift Pumping System.
3.—Supply of Duplex Steam Pump.
4.—Supply and erection of two H.R.T. Boilers and Stack.
5.—Supply and erection of compound vertical steam engine.
6.—Supply and erection of Generator, Exciter, and Switchboard.
7.—Supply of poles, arms, hardware, copper wire, transformers and meters.
8.—Supply of Series Tungsten street lighting apparatus.
9.—Erection of Pole Line.

Tenders must be accompanied by an accepted cheque for five per cent. of the amount of the tender, or alternatively by the bond of an approved guarantee company.

Plans and Specifications and other information may be obtained at the offices of the Consulting Engineers at Winnipeg and Calgary. A deposit of $25 will be required on Contract No. 1, which will be returned to bona fide tenderers on return of the plans.

The Corporation do not bind themselves to accept the lowest or any tender.

FOR SALE.—Complete Sewer and Water Contractor's outfit, including one Parsons' Trench Excavator, Trench Braces, Fire Pots, Pumps, etc. For price and terms apply to Navin Bros., Contractors, Moose Jaw, Sask.

FOR SALE at a snap: 60-H.P. Cowan and Co. engine and 80-H.P. Cowan and Co. boiler. Write for particulars, J. F. Barnard and Son, Spencerville, Ont.

WANTED.—A second-hand handing-up machine; state make, price and time used. Box 74, *The Canadian Engineer*, Toronto.

QUOTATION WANTED.—For steam boiler; delivered Norwood; twenty horse-power; steel, tubular, also firebox type; give dimensions. E. J. Laing, Secretary, Board of Education, Norwood, Ont.

WANTED.—Left-hand water wheel (flume wheel), to give 25- horse-power under twelve feet head; must be in good condition. Box 76, *The Canadian Engineer*, Toronto.

CORLISS ENGINE—16 x 36—new two years ago; very reasonable. Box 82, *The Canadian Engineer*, Toronto.

FOR SALE.—Lidgerwood cableway, capacity 10 tons on single line; 14-in. x 28-in., double reversing engine, three grooved drums 50-in. diameter, steel gears 72-in. diameter. Box 78, *The Canadian Engineer*, Toronto.

FOR SALE.—Quantity of steel pipe, four feet diameter, ¼-in. thick, cut to any length to suit purchaser. In A1 condition. Address Box 80, *The Canadian Engineer*, Toronto.

FOR SALE.—Steam Barge, sand dredge, 2 deck scows, 1 barge. For full particulars apply to Box 88, *The Canadian Engineer*, Toronto.

FOR SALE.—3 second-hand contractor's Dinky Vulcan Locomotives in first-rate condition. One 9 in. x 14 in. and two 10 in. x 16 in. Also a 50-ton Steam Shovel, and some contractor's Dump Cars. Apply to The Canadian Fairbanks-Morse Co., Limited, 444 St. James St., Montreal.

WANTED.—A second-hand centrifugal pump, 6,000 to 10,000 gallons capacity, electric motor or gasoline driven, direct connected. Address Box 90, *The Canadian Engineer*, Toronto.

CURRENT NEWS.

Edmonton, Alta.—One and a half million dollars is the amount by which the civic authorities have decided to cut the construction programme for the present season in view of the present state of the money market. Since Kleinworts, of London, the purchasers of the city's debentures, warned the city that they might be obliged to fall back on the "war" clause in their agreement, the administration has decided to retrench where possible. All heads of departments have reported where work might be curtailed without serious injury and work will be cut accordingly. Eight hundred thousand dollars will be saved in connection with the street railway department, the electric light, telephones and fire department, while plans for sewer extension will be modified and some of the paving work postponed.

Kerrisdale, Point Grey.—There seems to be a misunderstanding by contractors as to the meaning of the advertisement calling for tenders for the building of a municipal incinerator. One tenderer appeared before the board of works recently and asked to be enlightened as to the requirements of the district. He was told that the municipality desired an incinerator capable of disposing of twenty-five tons of garbage daily and must be so constructed that equipment for disposal of another twenty-five tons per day can be added. Each tenderer will be required to submit his own specifications and plans, for there is such a large number of incinerator equipments that no particular type was specified by the council.

London, Eng.—A contract of over £1,000,000 has been signed for the construction of a railway and new harbor on the west coast of Ireland in connection with the All Red route scheme, which the Canadian Government has now approved. The railway will run from Collooney to Black's Bay, County of Mayo, which is to be the port for the steamers which will make the run to Halifax in three and a half days.

ENGLISH ENGINEERS FOR UNDERWRITERS' LABORATORIES

Messrs. Heap and Digby, of London, England, have recently been appointed engineers in Great Britain to the Underwriters' Laboratories, Incorporated, Chicago, and are therefore in an excellent position to approve and inspect apparatus made in Great Britain for the Canadian market, to ascertain if it complies with the requirements as laid down by the National Board of Fire Underwriters.

Mr. Pollard Digby has been engaged in consulting practice for ten years, during which time he has inspected a great deal of electrical machinery for the Indian government, for South American railway companies, as well as a number of the South African mining companies.

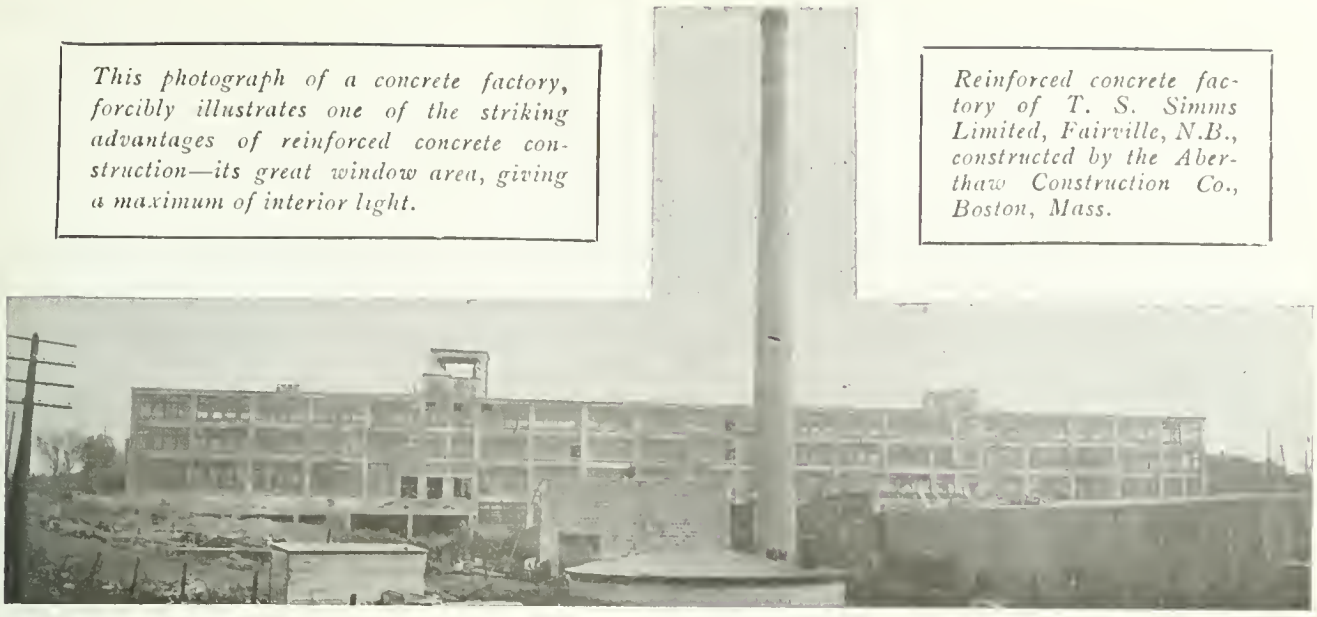
Mr. Digby is an associate member of the Institution of Mechanical Engineers, and also an associate member of the Institution of Electrical Engineers.

Mr. Arthur C. Heap was, previous to joining Mr. Digby last year, engaged for something like twenty-five years as a manufacturer of all types of electrical machinery, and therefore familiar with the details of construction, design and testing. He is a member of the Institute of Electrical Engineers.

The firm has a fully equipped laboratory where all the testing is done. They also have a branch office in Manchester, and Mr. Heap, the senior member of the firm, has for some years now made periodical visits to the United States and Canada, and is therefore in a position to fully understand Canadian requirements.

This photograph of a concrete factory, forcibly illustrates one of the striking advantages of reinforced concrete construction—its great window area, giving a maximum of interior light.

Reinforced concrete factory of T. S. Simms Limited, Fairville, N.B., constructed by the Aberthaw Construction Co., Boston, Mass.



Concrete Factories are Most Efficient

The efficiency of a machine is the ratio of the amount of work a machine does, to the amount of work required to operate it. The output is equal to the input minus the work lost or wasted. The less wasted the greater the efficiency.
In the same way the efficiency of a factory may be defined as the ratio of output to input. Output, financially, is increased by reducing unnecessary expenses.

Concrete Stops Wastes

Concrete buildings are proof against fire, water and vermin. They give the maximum light and are sanitary. They resist vibration, and are permanent and durable.

Fire-proofness reduces insurance rates. Water or liquids used in certain processes will not leak through floors to destroy valuable goods below. Rats and other vermin find no place to live in a concrete building, thus eliminating losses from this cause. Maximum light and sanitary conditions increase efficiency of employees. Lack of vibration reduces wear and tear on machines. Permanency and durability reduce depreciation.

The way in which concrete stops these leaks is fully described in our handsomely illustrated 224 page book, "Factories and Warehouses of Concrete." It contains photographs and data of factories and warehouses for all classes of industries.

The value of sandstone production in 1911, according to the statistics contained in the annual report on mineral production by Mr. John McLeish, B.A., was reported as $451,183, being a slight falling off as compared with the production in 1910, which was valued at $502,148. The greater part of the sandstone quarried is used for building purposes, though small quantities are also used as rubble and for paving purposes. Of the production in 1911, building and ornamental sandstone was sold to the value of $391,784, or 86.8 per cent. of the total sandstone sales. This amount comprised $86,502 in rough stone and $305,282 in dressed stone sold by the quarry operators. The production in 1910 of building and ornamental stone was valued at $454,220, comprising $118,364 in rough stone and $335,856 in dressed stone.

MARKET CONDITIONS

Montreal, July 19th, 1913.

Prices hold very steady, being again unchanged, as follows:—

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is unchanged, being now per 100 lbs., as follows:—¼-in., $5.30; 5-16-in., $4.70; ⅜-in., $3.90; 7-16-in., $3.65; ½-in., $3.55; 9-16-in., $3.45; ⅝-in., $3.40; ¾-in., $3.35; ⅞-in., $3.35; 1-in., $3.35.

Copper.—Prices are 16¾c. Excellent demand.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are: Queen's Head, $4.35; Colborne Crown, $4.25; Apollo, 10¾ oz., $4.25. Add 25c. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lead.—Prices are firm at $5.35.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft. x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is active and strong:—$36 for 6 and 8-inch pipe and larger; $37 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 73½ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73½ per cent. for black and 63½ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, July 23rd, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—¼-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 65c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.80, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1¼c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 7.5c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $6, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, July 22nd, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bare.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil; 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅞, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.60; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50: galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8¾ to 15c. per pound

An Engineering Weekly

THE DESIGN OF CENTRAL HEATING SYSTEMS

PART III.

THE UNDERGROUND TRANSMISSION SYSTEM CONTINUED—FORMS OF CONDUIT IN USE AND THEIR COMPARATIVE COSTS—THERMOSTATIC CONTROL

By A. G. CHRISTIE, M.E.,

Assistant Professor of Steam Engineering, University of Wisconsin.

The method of installation of the piping system and its protection must be of such a character that settlement of the trench or the pressure of the earth will not cause the pipe to become out of level or alignment. The pipe must be free to expand and there must be no restriction to this movement or some parts shall surely fail. The

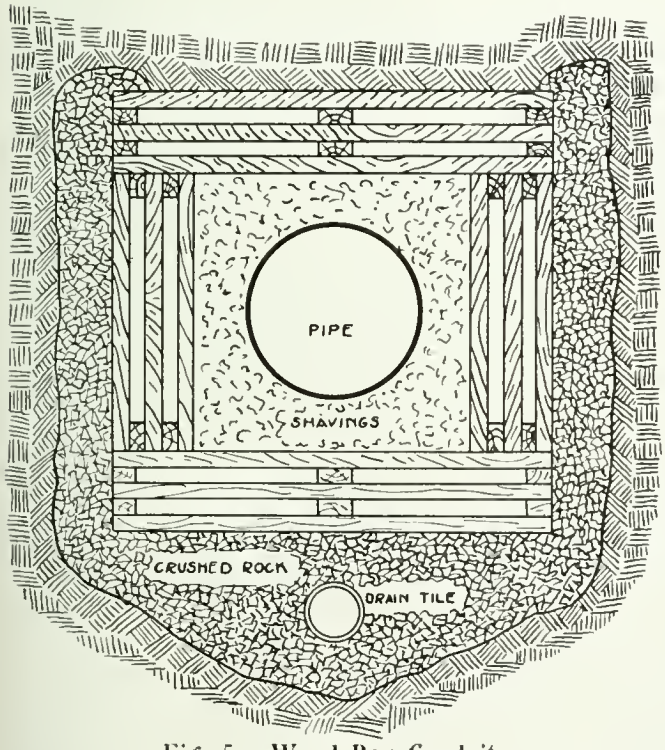

Fig. 5.—Wood Box Conduit.

insulating material and the conduit itself which protects the pipe must be of such a nature that it will not be affected by temperature changes in the pipe or in the earth. Otherwise cracks in the conduit will occur. These cracks allow water to seep in and not only to destroy the insulating material, but also to increase the line losses. All steam pipes should be carefully graded to the low points of the system where automatic steam traps should be placed in the manholes to remove the condensed steam and discharge it into sewers.

The earlier heating systems were usually provided with conduits built up of boards and paper with air spaces between and filled, as a general rule, with oiled shavings, as shown in Fig. 5. These conduits were very cheap in first cost, and gave good service when new. However, in a few years the oil commenced to distill out of the shavings and the wood started to decay, especially when laid in certain soils. A very uncertain factor was

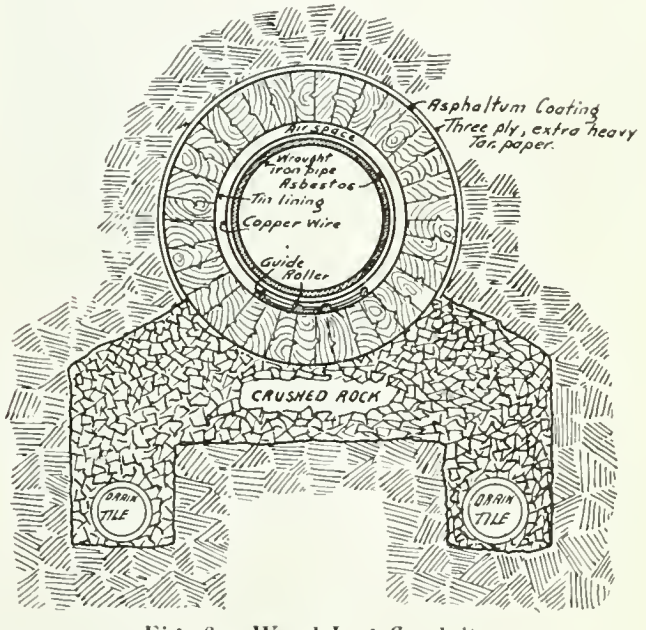

Fig. 6.—Wood Log Conduit.

the variation in decay in the length of an ordinary system due to variation in soils. Thus such systems became more inefficient with age, while the heating load, as a general rule, increased. It was also found hard to keep these conduits watertight. Their life has been stated to be anywhere from 15 to 25 years, depending on the soil surrounding them. After such experiences with this form, engineers have turned to other classes of conduit not so subject to decay or decrease in efficiency with age.

An improved form of construction is shown in Fig. 6, known as the "wood-log" conduit. It consists of white pine staves which have been thoroughly air and

kiln dried, cut to segmental section, and bound together into a circular form by heavy steel banding wires. These staves are provided with tongue and grooves, as shown. The outside is waterproofed by tar and usually an additional waterproof tar-paper covering is provided. The inside is lined with tin to cut down radiation losses and prevents any charring of the wood which might occur. The sections of casing can be obtained in lengths up to eight feet and are fitted together with mortise and tenon joints four inches long. The shell is usually four inches thick. The pipe is generally of wrought iron or steel, and all joints not adjacent to special fittings are made with heavy, long pattern couplings. The pipe itself is frequently wrapped with a special winding of asbestos paper secured in position by copper wire. Metal sealing rings are used at the joints of the casing when a watertight construction is desired. Girders and rollers for supporting the pipe are placed about eight feet apart. Special fittings are enclosed in watertight brick boxes

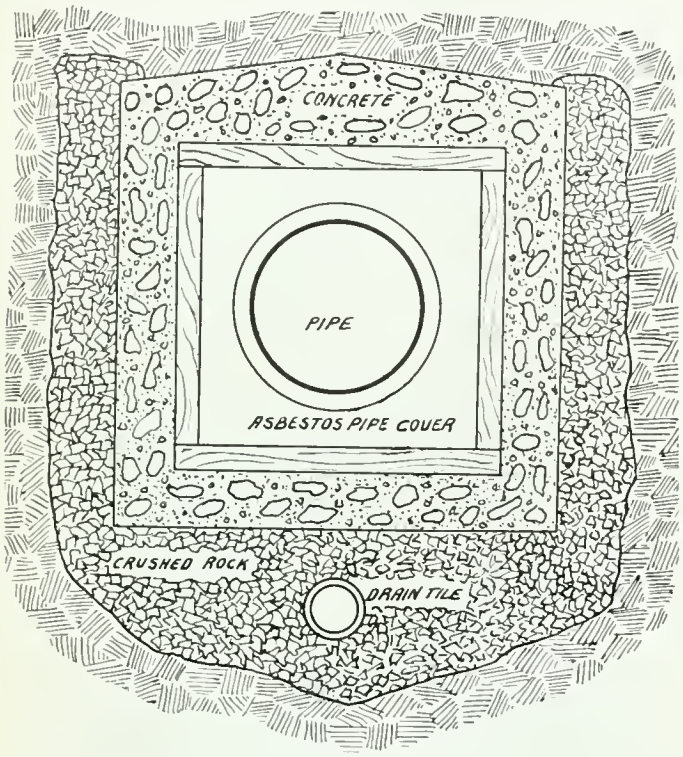

Fig. 7.—Concrete Conduit.

filled with oil-soaked shavings to prevent radiation losses. This conduit must be well underdrained to be efficient, which is usually done by means of single or double lines of 4-inch farm drain tile. It is fairly cheap and quite efficient, and can be readily taken up and repaired. The main objection to this construction is its deterioration, which is more or less rapid. In summer, when the heat is off the system, the wood is said to absorb moisture either from infiltration, from the ground, from leaky sewer pipe, or from broken water mains. The consequent swelling of the wood stretches the wires so that when hot and dried out again they are loose and allow the joints to open. The conduit is not then waterproof and the heat losses consequently increase. It has been noted in several cities that this wooden conduit deteriorates much more rapidly when laid under pavement or in cinders than when under sod.

Another form of conduit that has been used in a few cases consists of one of the wooden constructions already described, surrounded by a concrete shell.

Several heating systems have been recently built with the pipe line covered with an asbestos or similar moulded covering, which is waterproofed. A wooden box is then built around this, as shown in Fig. 7., and the whole then enclosed in a concrete box, thoroughly waterproofed and well underdrained. In some constructions oiled shavings have been used instead of the moulded covering, though less efficient. Concrete alone is not a good insulator so that dependence must be placed on the material surrounding the pipe. This conduit is expensive to lay, but is very enduring and maintains its high efficiency if it has been thoroughly waterproofed when laid. The principal objection to it is the difficulty of getting at the line for repairs or alterations.

The Milwaukee Central Heating Company use a type of conduit similar to Fig. 7, except that they install cast iron pipe with universal joints to carry the steam. This company has about 42,000 feet of main in service and have tried three different types of conduit. Their experience has led them to consider this type superior to either the wood-log construction or the concrete conduit filled with oiled shavings.

Another form of conduit, used at Beaver Dam, Wis., consists of hollow building tile in place of the concrete on the sides and top, as in Fig. 7. If this is once opened for inspection or repairs the tile is rendered useless. It has also been noted that tiles are liable to break in service, and, on the whole, this conduit has not proven very satisfactory.

Recent practice in heating systems has tended towards the adoption of the split glazed tile conduit shown in Fig. 8. The pipe is covered with a moulded or asbestos covering waterproofed by tarred paper or other means. A dead air space is provided between the covering and the tile. The joints of the tile are cemented together when the conduit is closed up. This conduit is very efficient as a heat insulator, cheaper than concrete, and more easily accessible for repairs. If the tiles are not first-class they break and thus destroy the efficiency of the system.

Cost of Conduit Construction.—The cost of conduit construction is a subject on which there is little information available. E. Darrow, in the Electrical World, April 6, 1911, in a paper on "Exhaust Steam Heating as Developed by a Large Central Lighting Station," gives the following costs for glazed tile conduits similar to that shown in Fig. 8.

Size, in inches	20	15	12	10	8	6	4
*Cost per ft.	$19.50	14.75	12.35	9.50	8.40	6.85	5.25

*Including trenching and paving.

For rough calculations this conduit may be said to cost $1 per foot length per inch diameter of steam main.

Conduits as shown in Fig. 7 are said to cost practically the same as the glazed tile. Wooden box conduits as shown in Fig. 5 are said to cost from 35 to 50% of the values given above. When hot water is used and two pipes are necessary, these costs have to be considerably increased.

There will be found in an article on "Wilkes-Barre's District Heating System," in the Engineering Record of September 14, 1912, the data reproduced in Table 4 on the costs of installing in Wilkes-Barre steam heating conduits of the type shown in Fig. 6. All re-paving was done by the city but the heating company was obliged to pay the city for permits to cut through the pavement at the rate of $3 per square yard for asphalt and $2.50 per square yard for brick, the measurements for which in-

cluded an excess of 8 inches beyond the actual cut and all tunnels and cuts under the pavement.

In the table, trenching includes cutting through the pavement, excavating the trench to grade, preparing subtrenches for underdrains, all backfilling and hauling away of surplus material. Laying pipe includes the furnishing and placing of all pipe, fittings, expansion devices, wood log, etc., the furnishing and laying of underdrains and all brickwork such as boxes around special devices and manholes for valves, traps and expansion joints.

The prices given were a fair average at the time the pipe was laid, but for use at the present time should be increased about 10 per cent. This work largely replaced a former system and was installed complete between May 31 and October 23 in 1911.

Temperature Control.—One of the most essential requirements of every well operated modern heating system is the installation of some form of thermostatic control valve on all service connections. In the case of residences, this valve may be located where the service enters the house and the thermostat may be placed in a central position in the living rooms. In office buildings each radiator is usually fitted with its own control valve and thermostat.

Thermostatic control with careful handling is said to reduce the charges for service by 6 to 8 cents per sq. ft. when on a flat rate basis. When meters are used, the savings that may be effected by this control system over hand-controlled service are as much as 15 to 30%, according to several central station managers.

However, when thermostats are installed on a system, the customer's attention should always be called to the fact that unless some simple rules are strictly followed the thermostat will waste heat. For instance, a window may be opened to air the rooms in the morning, and as the thermostat maintains a constant room temperature, this window may be left open for a considerable period. This would result in an enormous waste of heat. With a flat rate the heating company loses by such practice, while the customer has to pay bills that are unduly high when meters are installed.

When air-controlled thermostatic valves are used on the system, an air line has to be laid from the central station along the side of the heating main with branches carried to each service. The compressed air in this pipe is usually at about 15 pounds pressure. Johnson, Powers or National thermostats may be used with this system. In some cases independent thermostats like the Sylphon Regithern are placed on each individual service.

Miscellaneous Central Plant Service.—Vacuum systems are now quite commonly used in large office buildings, stores, libraries, private residences, etc., for cleaning and dusting. It has long been known that one of the cheapest means of transmitting energy is by the use of compressed air. In the case of vacuum the air is much less dense than when the air is under pressure and the losses are correspondingly reduced. It has, therefore, been proposed that the central heating company might in-

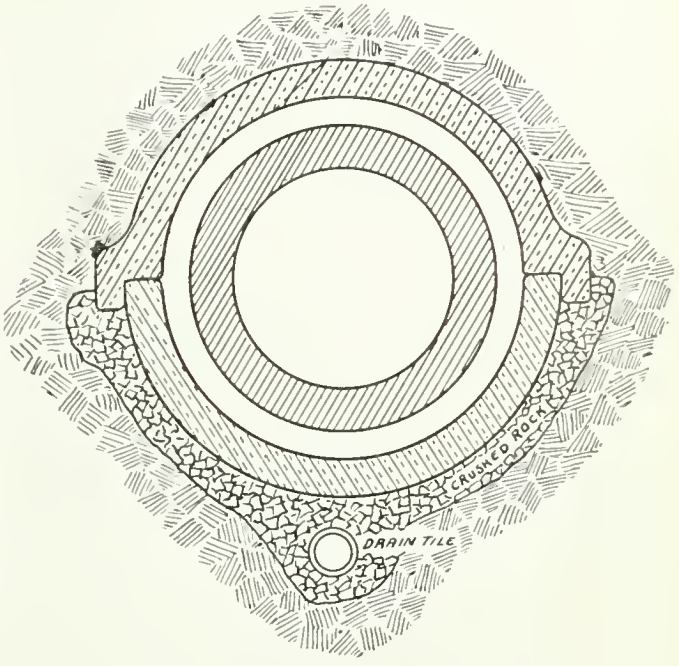

Fig. 8.—Split Glazed Tile Conduit.

stall a system of vacuum piping together with their heating system, and thus be prepared to furnish service to customers over certain periods of the day at a flat rate. No information has come to hand concerning such a

Table 4.—Conduit Costs at Wilkes-Barre.

Size, in inches.	Pavement.	Length, in feet.	Cost: Re-paving.	Trenching.	Laying pipe.	Incidentals.	Total.	Per lin. foot.

					Total cost of work		$138,328.95	

service at present in operation, though large hotels use these systems. However, the possibilities of such a system warrant a careful investigation of the project.

It has also been suggested that a hot water system might be supplied with cold water to cool the buildings during the intensely hot summer weather. Such results could be obtained by simply pumping cold water through the system if it were available or a system of refrigeration could be installed to artificially maintain the desired temperature. Such cooling service has been provided in some first-class hotels and in some theatres that run during the summer. Usually, however, the cooling of buildings is secured by passing the ventilating air through cold water sprays. While such cold water service as has been suggested would be welcomed by most people during the intensely hot summer weather, it is questionable whether this could be made profitable. It would be decidedly a luxury and not a necessity, as heat is in winter.

Ice-making plants have already been installed by several heating companies and many more are considering the advisability of such plants. These ice plants are run only during the summer season, and as they are usually of the absorption system, the exhaust steam is used which in winter goes to the heating system. As the electric load is frequently light during the summer months, in some cases compression machines have been installed. However, many decided improvements have been made of late years in the absorption system, and as exhaust steam can be readily used in it there is every probability that it will be used to a greater extent in the future than in the past.

Among the factors that should be considered when it is proposed to add an ice-making plant as an auxiliary to a central heating plant, the following should receive careful attention:—

1. The first cost and up-keep of the ice-making plant.
2. The probable demands for ice.
3. The competitive prices for ice.
4. The cost of making and delivering ice.
5. The power or exhaust steam available during the summer months for ice-making purposes.

A conservative estimate of the net profits to be derived from such an auxiliary plant is the real index that will show whether or not such installation is warranted.

Measuring and Charging for Central Station Service.—When central heating systems were first installed, charges for service were made by one of the following methods. At first, a fixed amount was charged the customer for the heating season equal to his average coal bill. This was unfair to the heating company, for it did not take into consideration the rising price of anthracite coal, the expense of removing ashes or the cleaning, repair and up-keep costs on the furnace used by the customer. This form of contract also encouraged the customer to minimize his former costs of coal. Besides this, customers usually practised strict economy in the use of heat from their own plants, but when this was supplied by a central station they were apt to be very wasteful. This last condition invariably occurs whenever charges are made on flat rates, and forms one of the strongest arguments against such systems of charging. A second system, which is still in use to a limited extent, provided for a fixed charge per unit of space heated. This method was often unjust, owing to the variation in the construction of the buildings heated, the height of ceilings, and use made of the building. A third method, which is still in use, consisted of a fixed charge per sq. ft. of radiation served. This system is not fundamentally correct, as it does not take into consideration the variation of heat demand with differences of glass and wall exposures, size of room, etc. However, if the radiators have been carefully designed for each room, the rates are, on the whole, very equitable. Such service should in every case be provided with thermostatic control, or otherwise the heat waste will be very great. While this method is still used to some extent with exhaust steam, it is used almost universally on hot water systems, for up to the present time no device has been placed on the market which will measure the heat supplied in hot water service. Such a meter is now being developed by Gebruder Sulzer at Winterthur, Switzerland, but has not yet been put on the American market. Some form of measured service is the best solution of the question of charges, both for the customer and for the company supplying heat.

The amount of heat supplied to a customer when exhaust steam is used can be determined by catching the condensation in a trap and discharging it through a hot water meter. The two meters of this type generally used are the "Simplex," made by the American District Steam Company, of Lockport, N.Y., and the "Detroit," made by the Central Station Steam Company, of Detroit, Mich. Other condensation meters of various types have been used and are being tried on heating systems with various degrees of success. All such instruments must be inspected periodically to see that bearings are not gummed up and stuck, that the dials are recording properly, that the spouts and nozzle are not choked up, and that the meter has not become out of level.

In some cases it is found desirable to measure the amount of steam supplied to a heating system, or, in the case of a large consumer, to measure the steam supply rather than the condensation. This can be done quite accurately by a steam flow meter. At the present time the type most widely used is that of the General Electric Company, Schenectady, N.Y. This meter is essentially a Pitot tube with either a mercury manometer or dial indicator or a special tilting device with a recording mechanism. Several tests have shown that these meters possess a high degree of accuracy for ordinary commercial work. Other steam flow meters that have been used include the Gebhardt, the St. John and the Sargent.

Water, either for boiler feed or for heating service, is most conveniently measured by the well-known Venturi meter, manufactured by the Builders Iron Foundry Company, of Providence, R.I. It is always provided with both an indicating dial and a recording dial of the circular chart type, and has an accuracy of within 2%. The Lea Water Flow Recorder, recently introduced into this country by the Yarnall-Waring Company, Philadelphia, Pa., is also used to measure and record the flow of fluids. In it the water passes over a V-notch and the quantity passing is recorded by means of a float and rack and pinion mechanism operating a pen on a paper chart driven by a clock. This apparatus cannot be used under pressure.

It will be noted that all condensation meters discharge to the sewer. This results in a certain loss of heat. When the supply of boiler feed water is bad, this loss of condensed steam is a serious matter and must be taken into consideration.

Probably the most important factor in the executive administration is the determination of equitable rates for service rendered. Rates, as already pointed out, should be based on the manufacturing cost of heat alone, independent of the financial benefits the company may derive

from the use of the steam generated to develop electric power. With such rates, reasonable profits will be assured irrespective of whether live or exhaust steam is used.

The rates to be charged for service will be dependent on: (1) the cost of coal; (2) the first cost and operating cost of the distribution system, and (3) the extent of the service and the number of customers. The rates in effect in cities throughout this country are very variable, as shown by the data presented in the "Report of the Committee on Rates" at the National District Heating Association's meeting in Detroit in June, 1912. From this report it can be seen that the average season on which heat is maintained on the distribution systems is 8.5 months. About 60% of the steam used in low pressure heating systems is exhaust steam, the remainder coming direct from the boilers through reducing valves. In almost every system reported the meters, where used, were installed by the operating company, though the taps were usually supplied by the consumer. The condensation is returned to the central station in about 20% of the plants. On steam systems customers are, almost without exception, required to install economizer coils at their own expense. About 50% of the companies charge the customer for service connections. The cost of coal ranged from $1 per ton to $8 per ton. The flat rates for low pressure steam ranged from 18 cents to $1 per sq. ft. per season. The flat rates, based on cubical contents, ranged from $2.50 to $8 per 1,000 cu. ft. per season. In meter rates there was an almost infinite variety from which no general conclusions of value can be drawn. In many hot water heating systems the rate per sq. ft. is limited by ordinance. The charges for hot water services on flat rates ranged from 10 to 30 cents per sq. ft., the average charge being about 20 cents per sq. ft.

DUNMORE IS RAILWAY TERMINUS.

Dunmore, Alta, is the eastern terminus of the Crow's Nest Railway. Starting at Dunmore, the Crow's Nest line opens up Southern Alberta country, and is the main thoroughfare to the rich Kootenay district, whose development in metals, timber and fruit is in its infancy.

Traffic increased to such an extent along this railway that the Canadian Pacific Railway decided to establish a station, round-house, and extensive yards at Dunmore, and the Canadian Pacific Railway estimates for 1913 show additional trackage and shipping facilities.

Dunmore is situated in easy access to raw material required for the manufacture of brick, pottery, tile, and terra cotta work; glass factories, iron plants, cement works, etc.

Mr. C. R. Ross of the Dunmore Development Company, Medicine Hat, will supply manufacturers interested with any information.

In his oxy-acetylene welding of copper, which is proving successful in German works, Carl Canzler has developed a process somewhat different from iron welding. Larger torches are necessary, and a liquid welding paste is employed, with a special copper welding wire. Formation of oxide is prevented by the paste. Copper plates an inch in thickness have been welded without difficulty, and the strength of the weld —which is not affected by acid—is found to be quite equal to that of solid copper in a continuous sheet.

ACTION OF SALTS IN ALKALI AND SEA WATER ON CEMENTS.

IN a recently issued bulletin of the United States Bureau of Standards, a paper is published containing results obtained from an investigation into the effect of alkali and sea water on concrete. The paper contains a good deal of experimental data which has been obtained during the past three years, and which is conclusive with respect to a number of points that have long been under discussion. The investigations were started in the structural materials testing laboratories of the Technologic branch of the United States Geological Survey, Mr. Richard L. Humphrey being in charge. They were transferred three years ago to the Bureau of Standards and the work continued by P. H. Bates, chemist, A. J. Phillips, assistant chemist, and R. J. Wig, associate engineer physicist, Bureau of Standards, under whose names the article appears. It is 157 pages in length and contains numerous illustrations, tables and diagrams. A few explanatory paragraphs, and the results which have been obtained to date, are given as follows:—

The disintegration of cement structures, when placed in contact with sea water, is a phenomenon which has attracted the attention of cement manufacturers and cement users almost from the first time that such material was used for marine construction. There are cement structures which have withstood the action of sea water for years and probably will continue to do so, yet there are structures which have failed; and it is also possible in the laboratory by artificial solutions to destroy almost completely a briquette, or cube, or cylinder made of cement mortars or concrete. The cause of this disintegration is not certain, though it is almost universally believed that it is the reaction of sulphate of magnesia of the sea water with the lime of the cement (formed during the setting) and the alumina of the aluminates of the cement, resulting in the formation of hydrated magnesia and calcium sulpho-aluminate, which crystallizes with a large number of molecules of water.

The other constituents both of the sea water and the cement are usually considered of little effect, though lately attention is being drawn to the fact that both sodium chloride and magnesium chloride rapidly attack the silicates.

Concrete structures have been made (especially in this country) which are resisting the attack of sea water to a marked degree. It is therefore not surprising that many engineers attribute the disintegration when it does occur to poor workmanship or materials, or to the abrasion of the sand or floating bodies in the water, and to the mechanical action of waves and frost action (as the disintegration usually takes place at or near the water line) rather than to any chemical reaction or crystallization due to such reaction.

It is not surprising that when cement structures were first placed in our arid regions this disintegration was not considered, though it was well known that these regions contain large quantities of magnesium sulphate, which, together with the sodium sulphate, forms the principal salts of the so-called "white alkali" in distinction from the black alkali, which is largely sodium carbonate. However, a short time after these structures were placed it was noticed that there was a softening of the mass along the water line and in due time this attracted considerable attention. It was investigated first by the Colorado State Agricultural College in the case of some dis-

integrated cement tile; and the Montana State Agricultural College in the case of the sewers and culverts of the city of Great Falls. These investigators, however, do not discuss the cause of the destruction other than to mention the sulpho-aluminate of lime formation, and in the case of the cement tile to mention that the silica and alumina were removed.

As the U.S. Government has been locating a large number of its irrigation projects in such regions, it was considered to be within the scope of the investigation of the Structural Materials Laboratories to make a study of this condition, which work was later consigned to the Bureau of Standards.

Scope of Investigations.—These investigations were planned for the purpose of determining the suitability and permanency of various cements in structures exposed to the chemical and mechanical action of sea water and alkali salts and, if possible, the cause of failure or disintegration of cements and concretes.

The study of the subject was begun in such a manner as to determine, if possible, just what reaction would take place when the salts, commonly present in sea water and alkaline soils, were allowed to act on cement mortars. In order that this study should be complete, information should be obtained not only as to what salts present in any solution might cause destruction, but also in what manner this destruction is being accomplished. Both chemical and physical investigations were made in the laboratory, and field tests in sea water were made. In both series of laboratory tests there have been used at various times, in addition to sea water from Atlantic City, solutions of sodium chloride, sodium sulphate, sodium carbonate, magnesium chloride, magnesium sulphate, ferrous sulphate, and also solutions in which there were present in equal parts by weight two salts as sodium chloride-sodium sulphate, sodium chloride-magnesium chloride, sodium chloride-magnesium chloride, sodium chloride-magnesium sulphate, sodium sulphate-magnesium sulphate, sodium sulphate-magnesium chloride, sodium chloride-sodium carbonate, sodium chloride-calcium chloride, sodium sulphate-sodium carbonate, magnesium chloride-magnesium sulphate. It will be noted that a solution of calcium sulphate was not used. This salt is comparatively insoluble, and a series of tests using it, even in a saturated solution, would hardly be comparable with the series in which the above were used and in which the solutions contained but 2 per cent. by weight of the anhydride salts. Moreover, when this solution contained the sulphuric anhydride radical, calcium sulphate would be formed in the cement.

With regard to field investigation, while much valuable information can be obtained from an inspection of existing concrete structures in sea water, it is practically impossible to obtain reliable and complete information after a structure is several years old as to the qualities of the materials used and the character of the workmanship in construction. The field laboratory was located at Atlantic City, N.J., as it was readily accessible and the sea water at this point was rather pure and undiluted from fresh-water streams. Atlantic City is situated about 150 miles south of New York on an island 7 miles long and from ⅛ to 1 mile in width, lying about 6 miles from the New Jersey mainland, with bays and salt marshes between. The building used as a laboratory, under which the exposure tests were made, was located on a pier 700 feet from shore, about 20 feet above mean tide with 20 feet depth of water beneath.

Concrete of varied composition was made with Portland, natural, slag, and other special sea-water cements under conditions approaching as closely as possible the various methods used in sea-water construction. Several thousand briquettes and other small test pieces were made and exposed to sea water in connection with the concrete tests for the purpose of comparing various types and brands of cements.

Conclusions.—The conclusions must be limited by the scope of this investigation and since the physical tests cover a period of exposure not exceeding 3½ years the conclusions should be considered as somewhat tentative.

1. Portland cement mortar or concrete, if porous, can be disintegrated by the mechanical forces exerted by the crystallization of almost any salt in its pores, if a sufficient amount of it is permitted to accumulate and a rapid formation of crystals is brought about by drying; and as larger crystals are formed by slow crystallization, there would be obtained the same results on a larger scale, but in greater time if slow drying were had. Porous stone, brick, and other structural materials are disintegrated in the same manner. Therefore, in alkali regions, where a concentration of salts is possible, a dense non-porous surface is essential.

2. While in the laboratory a hydraulic cement is readily decomposed if intimately exposed to the chemical action of various sulphate and chloride solutions, field inspection indicates that in service these reactions are much retarded if not entirely suspended in most cases, due probably to the carbonization of the lime of the cement near the surface or the formation of an impervious skin or protective coating by saline deposits.

3. Properly made Portland cement concrete, when totally immersed, is apparently not subject to decomposition by the chemical action of sea water.

4. While these tests indicated that Portland cement concrete exposed between tides resisted chemical decomposition as satisfactorily as the totally immersed concrete, it is felt that actual service conditions were not reproduced, and therefore further investigation is desirable.

5. It is not yet possible to state whether the resistance of cements to chemical disintegration by sea water is due to the superficial formation of an impervious skin or coating, which is subsequently assisted by the deposition of shells and moss forming a protective coating, or by the chemical reaction of the sea salts with the cement forming a more stable compound without disintegration of the concrete, or by a combination of both of these phenomena.

6. Marine construction, in so far as the concrete placed below the surface of the water is concerned, would appear to be a problem of method rather than materials, as the concrete sets and permanently hardens as satisfactorily in sea water as in fresh water or in the atmosphere, if it can be placed in the forms without undue exposure to the sea water while being deposited.

7. Natural, slag, and other special cements tested in concrete mixtures showed normal increase in strength with age both in sea water and in fresh water.

8. In the form of neat briquettes most of the Portland cements of high iron content, several of the cements of high or normal alumina content and one special slag cement did not show any marked difference in tensile strength whether exposed to fresh or sea water for all periods up to two years. Other cements of various com-

positions showed signs of disintegration after a few weeks.

9. All cements resisted disintegration in sea water better in mortar mixtures than in the form of neat briquettes. In most cases the mortar briquettes had normal strength up to 2 years' exposure.

10. The physical qualities of the cement, which depend essentially upon the method of manufacture, would seem to determine its resistance to decomposition when brought into intimate contact with the sulphate and chloride solutions.

11. Contrary to the opinion of many, there is no apparent relation between the chemical composition of a cement and the rapidity with which it reacts with sea water when brought into intimate contact.

12. Tricalcium-sulpho-aluminate could not be formed, and therefore disintegration could not result from this cause.

13. In the presence of sea water or similar sulphate —chloride solutions:

(*a*) The most soluble element of the cement is the lime. If the lime of the cement is carbonated it is practically insoluble.

(*b*) The quantity of alumina, iron, or silica present in the cement does not affect its solubility.

(*c*) The magnesia present in the cement is practically inert.

(*d*) The quantity of SO_3 present in the cement up to 1.75 per cent. does not affect its solubility, but a variation in the quantity present may affect its stability by affecting its rate of hardening.

14. The change which takes place in sea water when brought into intimate contact with the cement is as follows:

(*a*) The magnesia is precipitated from the sea water in direct proportion to the solubility of the lime of the cement.

(*b*) The sulphates are the most active constituents of the sea water and are taken up by the cement. Their action is accelerated in the presence of chlorides. No definite sulphate compound was established.

(*c*) The quantity of chlorine and sodium taken up by the cement is so small that no statement can be made as to the existence of any definite chloride of sodium compound formed with the cement.

15. The SO_3 added to a cement in the plaster to regulate the time of set is chemically fixed so that it will not go into solution when the cement is brought into intimate contact with distilled water.

16. Metal reinforcement is not subject to corrosion if embedded to a depth of 2 inches or more from the surface of well-made concrete.

An economical mine telephone system, already at work in a Prussian mine, has been brought to notice by O. Dobbelstein, a German electrical engineer. Any of the continuous lines of metal extending into the mine—such as rails, air or water pipes, or cables—may be used as a conductor, and the other side is earthed in the usual way, although the metal is already connected to earth. The usual telephone receiver is used. Current is supplied by a battery of 12 volts, and in the secondary circuit an induction coil is used. As the current is not sufficient to ring a bell, a form of relay is necessary. The telephone current energizes a weak magnet, and this vibrates a metal disc, which acts upon the special circuit to ring a bell. Temporary telephones may be quickly put in place, or the installation may be of permanent kind.

PAVEMENT SUB-GRADE.

By S. J. Van Ornum,
Consulting Engineer, San Francisco, Cal.

Engineers who have charge of road building have, as a rule, given slight attention or thought to the proper preparation of the earth sub-grade upon which pavements are constructed. It is obvious that the earth under a pavement sustains the weight of the traffic, and if the earth sub-grade is not prepared properly and compacted sufficiently to sustain such loads, irregularities and depressions will gradually appear in the pavement. The official organ of the League of California Municipalities contains an article in its July 13th issue by Mr. Van Ornum which brings up strongly the necessity of carefully constructed sub-grade and carefully prepared specifications covering the same.

The pavement base provides a stable material upon which to construct the wearing surface, and also equalizes and distributes on the earth sub-grade, the loads subjected to the pavement by the traffic.

The weight of loads hauled by wagons and trucks has increased rapidly in the past few years, and especially is this true since the automobile truck has become so successful. Loads as great as ten and twelve tons are now hauled by automobile trucks over pavements which were not constructed to properly withstand such weights. Great care should, therefore, be taken to provide a sub-grade so prepared and compacted that it will sustain the heaviest loads imposed upon the pavement without injury to the base or wearing surface. Recent reports from New York and London state that the excessive loads transported over some of the streets of these cities have caused serious injury to the concrete base. One street pavement in London, which for many years has carried a very heavy street traffic without apparent damage, shows signs of failure since automobile 'bus lines have been running over it, and an examination discloses the fact that the concrete base has badly subsided.

Although engineers realize the necessity of a properly compacted paving sub-grade, yet, in preparing specifications they give slight consideration to this phase of paving construction, with the result that the section relating to the rolling of the sub-grade is generally inadequate and often not sufficiently explicit to obtain a hard and firm sub-grade. When the engineer has implied authority, the phrase "rolled to the satisfaction of the engineer" is quite general. One paving specification recently examined simply states that the sub-grade "is to be compacted by rolling or tamping," but failed to place any conditions or restrictions upon such rolling or the weight of the roller to be used. Another specification for the construction of a standard pavement required the sub-grade "to be compacted by rolling and tamping," and the rolling "to be done by a steam roller of a weight not less than five tons." A five tandem roller has an effective compressive weight of approximately 175 pounds per lineal width of tire, while the wagons hauling the materials over the sub-grade for the paving of the street exert a pressure of over twice this amount and loads as great as one thousand pounds per lineal inch width of wheel tire are at the present time hauled over pavements.

A light roller will not sufficiently compact the earth, nor will it disclose any local weakness in the sub-grade, such as carelessly refilled pipe trenches or an improper character or condition of material immediately underneath

the surface of the sub-grade, but will simply form a slight surface crust which has insufficient strength to sustain heavy loads. The writer has observed standard pavements badly subsided and shattered and their life greatly decreased due entirely to the faulty preparation of the sub-grade.

Heavy rollers are so constructed that the effective rolling is accomplished by the rear two wheels and the weight is generally distributed so that approximately one-third the weight of the roller is carried by each wheel. Specifications for compacting sub-grades in general require the use of a certain weight of roller expressed in tons, or provide a minimum weight per lineal inch width of roller tires. Road rollers are manufactured with several widths of rear wheels, and by merely specifying the weight of the roller the compression per lineal inch width of tire can vary to a considerable extent, and thus a heavy roller with wide tires will not give as much actual compression as one weighing two tons less which has narrow tires. On the other hand, a heavy roller may be specified, which with narrow tires gives an excessive weight and might endanger water and other pipes if the ground be in a loose and unstable condition. The minimum and, in unfavorable soil conditions, the maximum compressive weight per lineal inch width of tire seems the more logical manner of specifying the weights, and obviates any uncertainty of the compression which will actually be used in rolling the sub-grade.

The slight increase of cost which thorough rolling entails is incomparable with the added durability and utility of the completed pavement resulting from a well compacted and solid sub-grade.

ELECTRIFICATION OF RAILWAYS.

In connection with the consideration which the Canadian Pacific Railway Company is giving to the electrification of a portion of its lines, it is interesting to note what American railways are doing in this respect. The day of electrification of steam roads is dawning. It has been stated that it costs about the same, mile for mile, to electrify as to build a new road, and the question is, therefore, almost entirely one of the advisability of heavy investment.

The Pennsylvania Railway is contemplating electrifying its line between Pittsburg and New York, a distance of over 400 miles, which will be at least double-track, and which will cost approximately $40,000 per single track mile.

In the Western States the Great Northern Railway, and the Chicago, Milwaukee and Puget Sound Railway have planned the electrification of 530 and 440 miles respectively, contracts having already been let for roadbed, power, etc. This revolutionary step is occasioned by the poor coal and water conditions with which steam locomotives have to contend in North Dakota, Montana and Idaho, and with hydro-electric power in abundance.

The Denver, Rio Grande and Western is electrifying one of its mountain divisions, 114 miles in length. Some 73 miles of mountain electrification for heavy coal haulage is a very interesting application of electricity in railroading which the Norfolk and Western Railway is planning in West Virginia. The new suburban electrified section of the Pennsylvania, extending from Philadelphia to Paoli, will comprise 70 miles of single track.

Electrifications which have already been made in the United States by steam railroads are as follows:—

	Miles of single track.
Baltimore and Ohio ..... The original electrification of the steam railroad. The pioneer user of heavy electric locomotives.	7.4
New York, New Haven and Hartford ..... Including 22 miles on the Hoosac tunnel route of the Boston and Maine, the lines from New York to Stamford, and Providence to Warren (38.5 miles and 109.3 miles); the Harlem River Branch, 141.4 miles; the line from Stamford to New Haven, now nearing completion, 210 miles, besides more than 50 miles of short lines, including a very complete system about Hartford.	594.8
New York Central ..... Two hundred and thirty-four miles out of New York City, 19 miles on the Michigan Central (Detroit River tunnel), and 118 miles on the West Shore Railroad between Utica and Syracuse.	371.6
Pennsylvania ..... Comprising 186.8 miles on the Long Island Railroad, 98.4 miles on the Pennsylvania's approach into New York, and 150.3 miles between Camden and Philadelphia.	435.5
Butte, Anaconda and Pacific ..... An ore-carrying mountain line	90.0
Southern Pacific ..... Suburban lines at Berkeley, Oakland and Alameda, Cal., close to San Francisco Bay.	96.0
Grand Trunk ..... Four miles of tunnel track (St. Clair tunnel) at Port Huron, Mich.	4.0
Erie ..... In Central New York to the south of Rochester.	40.0
Great Northern ..... The electrification of the Great Northern Railway's cascade tunnel, between Leavenworth and Skykomish, about 100 miles east of Seattle.	6.0

Word comes from London that Dr. Goldschmidt, the inventor of a new system of wireless telegraph which, it is said, will revolutionize such communication, has telegraphed his London agent that he has satisfactorily established communication between Neustadt, Ruebenberg, near Hanover, Germany, and Tuckerton, N.J., for two days during the day time, when the power employed at Neustadt—namely, 150 kilowatts, was more than sufficient for the distance of 3,900 miles. In the tests the new "singing wheel" used in this invention showed itself to be capable of such delicate adjustment that secret messages can be sent inasmuch as it can be varied and adjusted instantaneously to any length of wave. The reception of messages is so delicate that an attempt to tap it would involve the necessity of another company tuning to within .0 per cent. of a Goldschmidt message in order to be able to receive anything that could be understood. An English company with a privately-subscribed capital of $5,000,000 will probably be registered shortly. Sir Oliver Lodge, the scientist, expresses the opinion that the Goldschmidt machine will rule the aerography of the future.

PUBLIC CONSTRUCTION CONTRACTS.

The special committee of the American Society of Engineering Contractors presented a report which contains a fund of suggestions concerning public construction contracts. The report, which was made by Mr. Wm. B. King, is not an exhaustive one, but serves well as a basis for further discussion among engineers and contractors. As appearing in the Journal of the society for March, it contains the following:—

1. Your committee thinks it impossible to submit a complete form to cover all phases of all engineering contracts, but a work of much value can be done by adopting some general principles and formulating them so that they may be made a part of substantially every contract.

2. Every condition of whatsoever character by which the parties are to be bound should be submitted to bidders as a part of the specifications on which they bid. The contract to be signed should be annexed to the specifications. In this way the bidder is not liable to be surprised by new conditions appearing in the contract submitted for his signature after his bid is made and accepted.

3. The greatest vice of contracts is uncertainty. In adopting any form of contract or specifications, every effort should be made to secure exactness of definition of the rights and duties of both parties.

4. Recognizing the impossibility of foreseeing every emergency, some authority must be devised for the determination of either unexpected physical conditions or unforeseen ambiguities in the contract.

5. The first requisite to this is promptness, so that work may proceed. This doubtless requires that all disputed questions shall be primarily settled by the engineer present on the work.

6. But, while the engineer is the best fitted person to reach a prompt decision, his relation to the owner unfits him for an impartial decision. There must, therefore, be some provision for an appeal to an impartial tribunal, and final settlement of all disputes by it.

7. Disputes should, as far as possible, be settled as the contract progresses, so that the parties can know how they stand. To this end, all matters of dispute should be reduced promptly to writing and all appeals from the engineer's decisions should be promptly taken.

8. Each party should assume full responsibility for his own share of the contract.

9. This involves the assumption by the owner of responsibility for the local conditions and for the borings or other explorations of the site. The contractor should bid on guaranteed local conditions, with an increase or reduction of price for variations from these. The locality belongs to the owner and the contractor should not be obliged to gamble on it.

10. The principle also requires that a contract should not both provide the exact details of construction and guarantee the result. If the contractor is to do the work according to exact plans furnished him by the owner, the owner should take the responsibility for the result. If the contractor guarantees the result, he should be free to adopt his own methods of construction.

11. The contractor, especially when bound by a time limit, should be given the utmost freedom as to the order and manner of doing the prescribed work.

12. Definite provision should be made for the assertion in writing of demands made by either party varying from the normal contract price. The contractor should give prompt notice of a claim for extras and the owner of a claim for a decrease or for the assessment of damages.

13. Some rule should be prescribed for the owner's protection in case of delay on the contractor's part, either by a right to annul the contract, or to take over the work in whole or in part, or to deduct actual or liquidated damages. The subject is one of great difficulty and needs most careful consideration.

14. The contractor should be protected from loss by delay of the owner or the owner's other contractors and provision made for settling such losses, without suit, where possible.

15. What is the proper amount of retained percentages? What should be the maximum part of the contract price to be retained until final payment? Differences of opinion should be adjusted and a uniform rule adopted.

16. Material men insist that the contract bond should provide for payment for materials and labor. This leads to greater security to the material men and consequently lower prices. But it is an unnecessary cost to contractors to establish credit. This subject needs the views of both sides.

17. Some contractors and engineers maintain that the contract conditions should be as brief as possible. Your committee believes that all subjects which experience has shown may produce conflict should be definitely disposed of by the provisions fixed in the contract, even if this extends its length.

18. After every effort has been made to avoid all uncertainty in the contract and to settle disputes as they arise, some honest differences of opinion as to the rights of the parties may persist to the end of the contract. The final settlement of uncontested matters should be made without prejudice to the right of the contractor to recover disputed claims in the courts. It has, unfortunately, become too common to declare that on final payment the contractor shall sign a release of all claims arising out of the contract. This is a one-sided and dishonest provision. When payment is earned by a fulfilment of the contract, it ought not to be denied because the contractor believes that he is entitled to more, nor should he be forced by necessity to waive access to the courts to correct wrongs done him in the course of the contract.

Your committee might extend this discussion much farther, but believes that enough has been said to show the difficulties of the subject and the need of full consideration. Many forms of contracts have been drawn by various authorities. The standard forms of the Royal Institute of British Architects and of the American Institute of Architects have much to commend them. One general remark may be made in regard to nearly all such forms—that they have been generally prepared by persons representing owners, such as architects and engineers, and that, however fair their intention, the inevitable tendency has been to protect the owner's rights at the cost of the contractor's.

Boiling an iron or steel article in a gallon of water to which has been added four ounces of phosphoric acid and an ounce of iron filings will give it a black, non-corroding coating.

Canada's waterpower is estimated at 16,600,000 horsepower, equal to an annual production of 367,000,000 tons of coal; only 1,016,521 horse-power has been developed.

THE DESIGN OF A REINFORCED CONCRETE ABUTMENT.

Application of Theoretical Formulæ to Practical Design.

By H. R. Mackenzie, B.A.Sc.

THE general dimensions for the abutment shown in detail in Fig. 1, as designed for general use, are from the set of standard abutments of the Board of Highway Commissioners for the Province of Saskatchewan. The distance from bottom of footing to grade level is taken as 24 feet. The spans allowed for are truss spans up to and including 175 feet. The bottom chords of the standard Petit truss bridges are 17 feet 6 inches centre to centre. The width and depth of bridge seat are constant and the wing wall of the abutments slope back at an angle of 30 degrees with the face wall and decrease in height at a 1½ to 1 slope.

The dead load for a 175-foot Petit truss span consists of steel, 1,250 lbs. per lineal foot, while the live load is assumed as 100 lbs. per square foot of floor, (16 feet wide), and a 25-ton traction engine, with two-thirds of its weight assumed to act on rear wheels, which are 30 inches wide and 8 feet centres; axles being 10 feet centres.

This abutment was designed by the aid of general usages and empirical formulæ, and it is the purpose of this article to investigate the design from the standpoint of theoretical formulæ.

Foundations.—When rock foundations are unattainable on account of the great depth of soil, piles are driven to increase the bearing capacity of the foundations. If the nature of the soil is accurately known, the number of piles required can usually be determined before the excavations are made. As a guide in determining the necessary increase in bearing capacity of a certain soil, or the allowable stress on foundations of other materials, Baker's and Rankine's tables of crushing strengths for various materials likely to be used as foundation beds for abutments are of great service.

It is the custom of the Board of Highway Commissioners for the Province of Saskatchewan to carry the excavation to such a depth that the top of the piles shall be below low-water level. This condition is not required in the case of concrete piles, but the equipment required in driving is more elaborate, and is usually not included in the plant of contractors doing this class of work, hence wooden piles of 25 feet in length with a minimum diameter at the tip of 6 inches, are always used under normal conditions. These piles are placed principally under the main buttresses, centre of wing walls, and toe of footings, and vary from three feet to five feet centres, according to the requirements of the specific case considered. Spacing is left largely to the judgment of the resident engineer.

Design.—The base is approximately one-half the height. Two buttresses support the bridge seat, and are placed directly beneath the centres of bearing of the bottom chords of the truss. A face wall connects these buttresses, which resists the lateral earth pressures transmitted through the earth. The face wall is continued forming the wing walls. The buttresses and the face wall rest on a continuous base which resists the earth pressures. At the back of the bridge seat is a parapet wall supported by the bridge seat, which runs into the wing walls and simply serves as a retaining wall to protect the bridge seat.

Parapet Wall.—This wall is designed as a cantilever beam connected by continuous reinforcement to the bridge seat. Its height is 2 feet 6 inches. We shall consider a strip one foot wide, assuming that the line of cleavage of material behind the wall is at a slope of 30 degrees to the horizontal, or that ϕ equals 30 degrees. Hence Rankine's formula for resultant earth pressure becomes,

$P = \frac{w.\ h.^2}{6}$, where h = 2.5, and w = 100 lbs.; and therefore, P = 104 lbs.

For live load pressure we will assume the worst possible case of loading, i.e., when rear wheels of 25-ton traction engine are just off the bridge. This live load of 33,000 lbs. we shall assume to be distributed on 6 linear feet of roadway. Therefore, the load per lin. foot of roadway equals $\frac{33{,}000}{6}$ equals 5,500 lbs.

This live load of 5,500 lbs. per lin. foot of roadway is assumed to be distributed over a distance equal to the out to out dimension of the rear wheels which is 10.5 feet, therefore, the vertical pressure due to live load equals $\frac{5{,}500}{10.5}$ equals 525 lbs. per square foot.

Horizontal pressure equals $\frac{525}{3}$ equals 175 lbs. per square foot. Bending moment of resultant earth pressure assumed to act at lower third equals

$$w.\ l. = 104 \times 10 = 1{,}040 \text{ in. pds.}$$

Bending moment of uniformly distributed live load of 175 lbs. per square inch equals

$$\frac{w.\ l.}{2} = \frac{175 \times 2.5 \times 30}{2} = 6{,}575 \text{ in. pds.}$$

Total moment = 1,040 + 6,575 = 7,615 in. pds.
Hence, from theory of beam, 108 b. $d.^2$ = 7,615; and d = 2.4 inches.

In order to secure against impact, and to protect the steel, this beam is made 6 inches thick.

Amount of steel required = 12 × 2.4 × .008 = .22 square inches per foot of wall. Use ¾-in. rods, (area = .44 sq. ins.) spaced 2 feet centre to centre. Also to resist cross bending, horizontal rods ¾-in. diameter and 15-in. centres are used.

Face Wall.—The face wall is designed as a horizontal beam supported by the buttresses. As buttresses are 17 ft. 6 in. centres, and assumed 4 feet wide, we have a clear span of 13 ft. 6 in. Consider a strip one foot wide at base of face wall, assuming the thickness of footing to be 1 ft. 6 in., the depth of fill at centre of strip equals 22 feet. Hence, $p = \frac{w.\ h.}{3} = \frac{100 \times 22}{3} = 733$ lbs per square foot.

The live load stresses are assumed to have become dissipated in the embankment before reaching this depth. Hence bending moment equals

$$\frac{w.\ l.}{10} = \frac{(733 \times 13.5) \times (13.5 \times 12)}{10} = 160{,}000 \text{ in. pds.}$$

Therefore, 108 b. $d.^2$ = 160,000, from which d = 11.2 ins.
Similarly we shall examine a strip one foot wide at depth of 15 feet. $p = \frac{w.\ h.}{3} = \frac{100 \times 15}{3} = 500$ lbs. per sq. ft.

Bending moment equals

$$\frac{(500 \times 13.5) \times (13.5 \times 12)}{10} = 109{,}500 \text{ in. pds.}$$

Therefore, 108 b. d.^{2} = 109,500 and d = 9.2 ins.

Area of metal required at this point, 9.2 × 12 × .008 = .88 square inches.

amount required to make the beam equally strong in tension and compression. The vertical reinforcement consists of ½-inch round bars at 12-inch centres.

Bridge Seat.—The buttresses are designed to carry the bridge loads directly to the base, hence the bridge seat has no direct load to carry; but it carries a portion of the overturning moment from the parapet wall and

PLAN OF REINFORCEMENT IN FOOTINGS

Fig. 1.—Standard Reinforced Concrete Abutment; Board of Highway Commissioners, Saskatchewan.

To ensure against impact and transmitted live load pressures, the face wall is made 9 inches deep at the top, tapering to 12 inches at base. The amount of reinforcement shown in drawing is much less than the theoretical also acts as a bond between the buttresses, thus adding to the stability of the structure as a whole. The depth of 8 inches employed is amply sufficient for these purposes. The vertical bars in parapet wall are bent and continued

across bridge seat, while the longitudinal reinforcement consists of ¾-inch round bars 12-inch centres.

Bridge seats are sometimes designed to carry the load of the girder to the buttress if the girder should be accidentally displaced. This is thought by the writer to be an unnecessary precaution, as when the bearings of the truss are anchored to the buttresses in the usual manner adopted by the commission, nothing short of complete failure would displace the truss. This, however, is not true of railway truss spans where, from the nature of the accidents that may occur, the bridge seat should be designed to sustain a possible displacement.

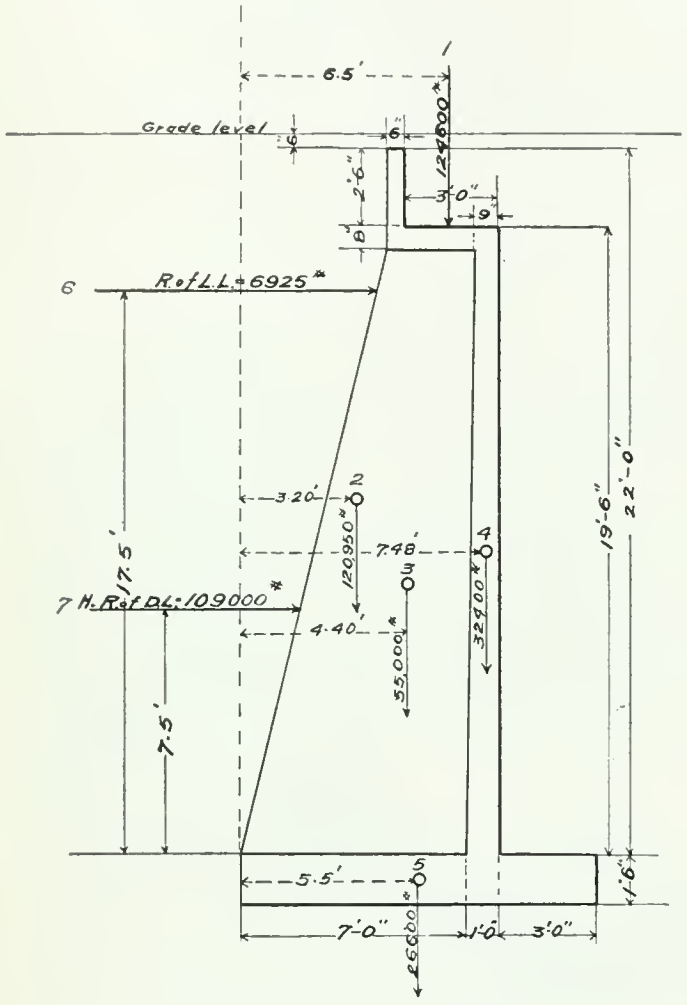

Fig. 2.—Section at Buttress.

Buttresses.—The buttresses are placed directly under the bed plates of the bottom chords of the truss. They are designed as cantilevers fixed at the base and are reinforced by bars placed in the rear, anchored in the base to take care of the overturning moment. The base of the buttress is large to secure the distribution of the abutment reaction over a considerable area of the footing.

Consider the required depth of buttress at the base: Depth to base of buttress = 22.5 ft. Therefore, resultant horizontal pressure on one foot of wall equals

$$\frac{w.h.^2}{6} = \frac{100 \times (22.5)^2}{6} = 8,437 \text{ lbs.}$$

Total width between wing walls equals 25 feet 10 inches.

Therefore, $\frac{25' \ 10''}{2}$ = 12.9 feet of wall supported by each buttress.

Therefore, the resultant dead load pressure on each buttress equals 8,437 × 12.9 = 109,000 lbs.

The bending moment of this resultant acting on an arm equal to one-third of the height equals 109,000 × 7.5 × 12 = 1,308,000 in. pds.

The live load of 5,500 lbs. per lin. foot of road, which, when assumed to be distributed over 10.5 feet giving a horizontal pressure of 175 lbs. per square foot, will decrease in intensity with the depth, but will consequently be distributed over a greater area of the wall. For these reasons we will assume that the total thrust due to live load can be approximated by considering it to act with an intensity of 175 lbs. per square foot at surface over a horizontal distance of 10.5 feet and diminishing to zero at a depth of 15.0 feet. Hence total live load pressure conveyed by face wall to each abutment

$$= \frac{87.5 \times 10.5 \times 15}{2} = 6,925 \text{ lbs.}$$

Distance of centre of gravity of live load pressures from base of buttress = 17.5 feet.

Bending moment of live load = 6,925 × 17.5 × 12 = 1,455,000 in. pds.

Total moment = 1,308,000 + 1,455,000 = 2,763,000 in. pds.

Therefore, 108 b. d.^{2} = 2,763,000 b = 4 feet, and hence, d.^{2} = $\frac{2,763,000}{108 \times 48}$ = 530. Therefore, d. = 23 ins.

Amount of steel required = 23 × 48 × .008 = 8.85 square inches.

Amount of steel from drawing equals 9 bars at 1″Φ = 7.07 square inches. But, in addition the these, there are four vertical bars ¾-in. rounds, placed on each side of the buttresses, which would more than supply the deficiency.

By similarly considering a section of buttress at a depth of about 12 feet, it will be found that approximately half the amount of steel required at base will be sufficient to resist the bending moment. Horizontal reinforcement is also used, but the area of such reinforcement cannot be easily calculated, and probably does not play any definite part in increasing the working strength of the buttress, except, in as far as the buttress may be considered, as a cantilever, supported by face wall, resisting lateral pressures at right angles to the centre line of the road.

No attempt is made to supply the theoretical amount of steel corresponding to the cross-sectional area of the buttress, as it is enlarged at the base to distribute the load within the safe bearing capacity of the foundation. The area of steel required to resist the bending moment can be computed, entirely apart from the required depth of the beam, by dividing the total bending moment by the perpendicular distance of bars from centre of base of face wall. This gives the required tensile strength which, if divided by the working stress per square inch of metal, will give the required area in square inches.

We shall now investigate the stability of the abutment at a section through one of the buttresses. Fig. 2 shows the dimensions at such a section as well as the position and intensity of the various forces due to live load and dead load stresses which act either directly on the buttress or are transferred to it by the base and face wall.

Force (1) = Abutment reaction of truss.

Force (2) = Weight of earth fill resting on buttress and projection of base pertaining to buttress.

Force (3) = Weight of buttress.
Force (4) = Weight of face wall, bridge seat and parapet wall pertaining to buttress.
Force (5) = Weight of base pertaining to buttress.
Force (6) = Resultant of live load pressures.
Force (7) = Resultant lateral earth pressures.

In calculating the intensity of these forces the weights of a cubic foot of earth and concrete were assumed to be 100 lbs. and 150 lbs. respectively, and each buttress is assumed to carry the forces acting on, and the dead weight of, one-half the area of base and face wall, etc., included within the out to out dimensions of the buttress, namely, 10.75 lin. feet.

The relative positions, and intensity of the resultants of the horizonal and vertical forces acting on the buttress were determined by the method of moments, and are shown in Fig. 3. The resultant "R" of these two forces was found by the solution of the triangle of forces, and equals 376,250 lbs. Its line of action cutting the base at a point 2.8 feet from toe. The resultant vertical pressure of 359,550 lbs. we shall assume to be uniformly distributed over a lineal distance of 10.75 feet. This assumption is considered rational on account of the binding action of the bridge seat and face wall being such as to allow of no movement of buttress apart from a displacement of the abutments as a unit. Also from the application of the formula

$$\frac{\overline{p}}{p} = \frac{1}{1 + \frac{x_0 x_1}{K^2}}$$

where $\overline{p}$ = Average pressure over rectangular cross-section
p = Maximum pressure on section
x_0 = Eccentricity
x_1 = Half the dimension of cross-section in the direction of the eccentricity,

we can assume the effective supporting width of the base to be 2.8 × 3 = 8.4 feet.

Therefore, $\overline{p}$ = the average pressure = $\frac{359,550}{10.75 \times 8.4}$ = 3,970 lbs. per square foot, and hence, p = pressure at the toe, = 3,970 × 2 = 7,940 lbs. per square foot, since the eccentricity is assumed to be ⅙ b.

The safe load per pile being assumed as 30 tons, and as area attributed to each pile is approximately 10 square feet, we have a bearing capacity of 6,000 lbs. per square foot due to piling alone. Also, as a conservative estimate we can assume the bearing capacity of the soil under ordinary conditions to be 25 lbs. per square inch, equal to 3,600 lbs. per square foot. Hence, total bearing power of foundation equals 6,000 × 3,600 = 9,600 lbs. per square foot. Therefore, the pressure at the toe of base is not beyond the resisting power of the foundation.

Wing Walls.—The wing walls are designed as cantilevers anchored at the base. Consider a strip of wall one foot wide, where height above footing is 15 feet. As wall is surcharged with material at natural slope the resultant earth pressure, $P = \frac{1}{2}$ w. h.^{2} cos.$^2\phi = \frac{1}{2}$. 100. (15)^2 (.886)^2 = 8,450 lbs.

No live load is considered at wing walls, hence total moment at base of wall = 8,450 × (5 × 12) = 507,000 in. pds.

Therefore, 108 b. d.^{2} = 507,000

$$d.^2 = \frac{507,000}{108 \times 12} = 392$$

d. = 20 in.

Area of steel required per foot of wall = 20 × 12 × .008 = 1.9 square inches.

The area of metal from drawing is only .44 square inches, and is constant from base to top of wall. This is apparently a mistake in design as bending moment decreases rapidly as surface is reached, the amount required at any particular point being determined by the method illustrated above.

Let us investigate the stability of the strip of wing wall under consideration. The dimensions, obtained from Fig. 1, are shown in Fig. 4.

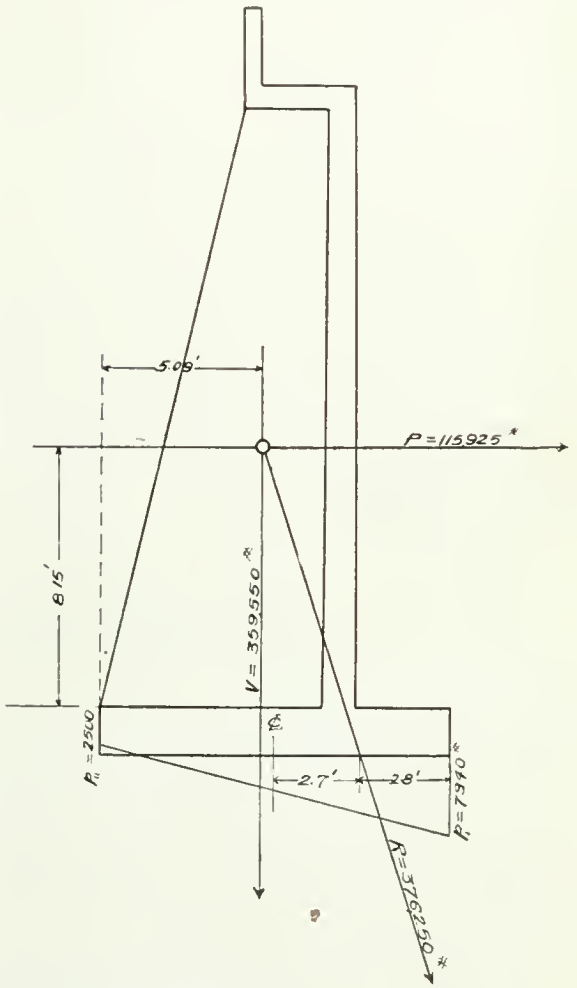

Fig. 3.—Resultant Forces at Buttress.

To find the resultant vertical force due to weight of wall and of area of earth resting on rear projection of base, we divide the wall into two parts, as shown, determining the weight and position of centre of gravity of each, also determining the weight of earth supported and its centre of gravity. The results obtained are shown in Fig. 4, and are based on the previous assumption that a cubic foot of earth and concrete weigh respectively 100 and 150 lbs. In order to find the position of the resultant of the three forces (1), (2) and (3), take moments about a vertical line through the heel.

Moment of force (1) = 8,320 × 2.33 = 19,400
Moment of force (2) = 1,120 × 5.57 = 6,250
Moment of force (3) = 2,370 × 4.65 = 11,000

$\Sigma x = 11,810 \qquad \Sigma m = 36,650$

$$y = \frac{\Sigma m}{\Sigma x} = \frac{36,650}{11,810} = 3.10 \text{ feet},$$

equal distance of resultant vertical force from axis of moments.

The position and intensity of the two forces affecting the stability of the wall are shown in Fig. 5. The resultant, "R," is found by solution of the triangle of forces equal to 17,500 lbs., and cuts the base 2.45 feet from the toe.

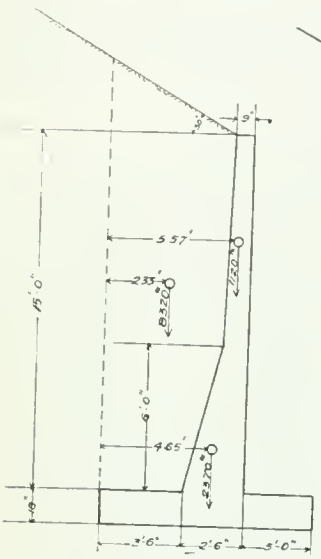

Fig. 4.—Resultant Vertical Force Due to Weight of Wall and of Earth on Base.

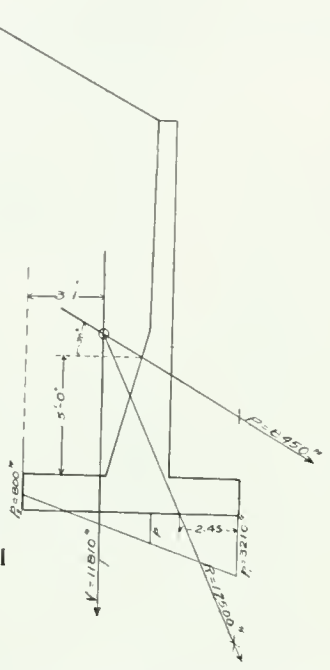

Fig. 5.—Positions and Intensity of Forces Shown in Fig. 4.

To find pressure on foundation at toe of wall, we shall assume, as in parallel case previously considered, that the effective width of supporting base = 2.45 × 3 = 7.35 feet. Hence, average pressure = $\frac{11,810}{7.35}$ = 1,605 lbs. The pressure at the toe equals twice the average pressure = 1,605 × 2 = 3,210 lbs., which is far within the bearing capacity of the assumed foundation.

Base—The base should be of sufficient width to properly distribute the load within the safe bearing capacity of the foundation. At the buttresses or any intermediate point the three-foot projection beyond face wall is subjected to an average upward soil pressure of 6,520 lbs. per square foot. This projection is assumed to act as a cantilever, and as the centre of gravity of the upward forces is found to be 1.58 feet from front of face wall, the moment in clockwise direction = 6,520 × 3 × 1.58 × 12 = 371,000 in. pds. Moment in opposite direction due to weight of projection = 12,100 in. pds. Hence, net moment = 371,000 — 12,100 = 358,900 in. pds. But, 108 b. $d.^2$ = 358,900, from which d. = 16.6 inches, as compared with total depth of 18 inches, as per Fig. 1. Area of steel required = .008 × 16.6 × 12 = 1.60 sq. ins. Area of steel from drawing equals 1-inch square bars at 8-in. o.c., equals 1.5 square inches per foot of base. The proper spacing of steel, according to our investigation, would be 1-in. square bars at 7-in. o.c.

Consider the shear at this section, thickness of base being 18 inches. The average shear on 12 inches equals

$$\frac{6,520 \times 3}{18 \times 12} = 90.5 \text{ lbs.}$$

As this exceeds the allowable shear in concrete, namely, 60 lbs. per square inch, it is necessary to supply shear reinforcement, apart from the area required to resist tension.

The base between buttresses behind the face wall is figured as a beam supported by the buttresses, to resist the upward or downward pressures, as the case may be. At any section between buttresses we have a net upward pressure behind the wall of 1,950 lbs. per square foot, and an average downward pressure of 2,000 lbs. per square foot on rear foot of base. As span is 13.5 feet,

$$\text{moment} = \frac{2,000 \times (13.5)^2 \times 12}{10} = 438,000 \text{ in. pds.}$$

But, 108 b. $d.^2$ = 408,000

$$d.^2 = \frac{408,000}{108 \times 12} = 337$$

d. = 18.35 inches.

Area of metal required = 18.35 × 12 × .008 = 1.76 square inches, as compared with total depth of 18 inches and area of 1.57 square inches of metal supplied, as per Fig. 1.

In order to take care of the reversal of stress in the rear of the footing it would be advisable to place reinforcing steel at the top and bottom of base plate.

The front and rear projections of base, in case of wing walls, are both designed as cantilever beams. Considering the front projection of the section shown in Fig. 5, we find that the average upward pressure to which the projection is subjected, equals 2,550 lbs. per square foot. The centre of gravity of these upward forces is found to be 1.63 feet from the face of the wall. Therefore, moment of upward forces equals (2,550 × 3) × (1.63 × 12) = 150,000 in. pds.

Resisting moment due to dead weight of projection equals (3 × 1.5 × 150) × 18 = 12,100 in. pds.

Therefore, net moment = 150,000 — 12,100 = 137,900 in. pds. But, 108 b. $d.^2$ = 137,900, from which d. = 10.3 inches.

Area of metal required per foot of wall equals 10.3 × 12 × .008 = .99 square inches.

Area supplied in Fig. 1 equals 1 square inch, and total depth of beam equals 18 inches, from which it appears that there is an excess of concrete at this point.

The design of the rear cantilever is exactly similar to the above and, as may be seen from the figure, the pressures are considerably less than in the case of the front projection. Hence it is evident that, if the same section be used throughout, it will be excessively strong, but perhaps permissible as it facilitates the construction.

The Transcontinental Railway Company, Ottawa, Ont., have recently purchased from the International Engineering Works, Limited, six locomotive boilers, 100 h.p. each. These boilers are to be installed in their various stations and roundhouses along the line.

EARNINGS AND INVESTMENT IN TRANSIT FACILITIES.

THE following is abstracted from a report by Mr. Bion J. Arnold on the transportation facilities of the city of San Francisco. The same traffic expert is investigating traffic conditions in Toronto at the present time, and his report concerning the service, etc., of the Toronto Railway Company will no doubt have a good deal to do with the purchase by the city of the Toronto Street Railway and the Toronto Electric Light Company, since it has been stipulated that they cannot be purchased separately. The following extract, which contains the major part of Mr. Arnold's conclusions and recommendations to the city of San Francisco, is likely, therefore, to be of interest:—

An analysis of growth shows that San Francisco is now growing faster than during the five years before the fire, and at a rate of increase of about 145,000 per decade. The real growth of the city, excluding the effect of the fire, has been at the rate of 54% for the last decade, as against 22% shown by the census. At the present time the city contains about 450,000 people. This population, on the conservative basis assumed, should double in 26 years, and should reach 1,000,000 people in 1945, although it may far exceed this.

San Francisco and the commuter district now has a population of 730,000 people, and has increased 48% in the last decade. This population should double in 23 years, reach 1,000,000 in 1919 and 2,000,000 in 1945.

In spite of this rapid growth, other large cities of the Pacific Coast are growing on the average at a rate probably 50% faster than San Francisco.

As a result of the fire, San Francisco lost 100,000 people permanently. The trans-bay cities gained in population by an amount practically equal to San Francisco's loss. But traffic statistics show that Oakland and its surrounding communities are becoming self-supporting to such an extent that the exodus from San Francisco has practically ceased, and that Oakland will go forward at a normal rate as a supplementary community.

One beneficial result of the fire was a general exodus of residents from the congested inner city to the suburbs, amounting to 66,000 people in the last census period. This has necessarily increased railway earnings and should therefore have made possible correspondingly improved service. The present distribution of population within the 30-minute zone is unusually uniform, except Chinatown and Japtown. The outlying distribution indicates that people will live where proper streets and car-service facilities are provided.

The growth and interchange of population within the district shows that the broader movements of population absolutely disregard municipal boundaries. The idea of a metropolitan district control for the development of utilities and industries is therefore of unusual necessity for San Francisco and the Bay cities.

A review of industrial growth shows that the period of great activity occurring just before the fire was practically recovered by 1910, and that commercial operations now generally exceed those of 1905. The fact that bank clearings suffered no perceptible depression during the disastrous year of the fire indicates the sustaining power of the financial credit of the community.

Manufacturing within the industrial district has alone failed to keep pace with the population within the last decade. In this respect the Bay cities have gained directly from San Francisco's heavy loss. The evident need for a more united industrial district points unmistakably to the practical value of the metropolitan district control idea already suggested.

An analysis of railway earnings shows that they are increasing in proportion to the square of the population; that is, when the population doubles, earnings quadruple. United Railroads earnings alone should double in the next 13½ years; that is, should reach $16,000,000 by 1924-25 and should quadruple by 1942. Earnings per capita are now the highest in the country—$20 per capita for all companies.

In extension of track mileage, San Francisco is at least six years behind the necessities of the growth in population. Trackage should extend at least as fast as the population, if not faster. The total track mileage is now about the same as before the fire, due to abandonments, and the last 15 years shows a slower growth than at any period of the city's history.

The present necessities for track extension require about 15 miles per year up to 1920. This will be just sufficient to complete the extension schedule recommended, and is also required to catch up with the normal growth in population. From 1868 to the time of the Market Street Railway Co. consolidation in 1893, track mileage was extended at the rate of 8.1 miles per year, during the maximum period, 16 miles per year. Since consolidation, the rate of growth has only averaged 3.6 miles per year.

The total operating equipment of all companies in 1911 was 676 cars. Prior to the fire there were many more cars reported, but of smaller capacity, averaging about 30 seats, as against 42 seats at the present time. Several hundred obsolete and worn-out cars were retired in 1907.

The total seating capacity at the present time appears to be about the same as before the fire, but it is a question whether the service capacity, in proportion to traffic, is as great in view of the increased schedule speed, owing to the exodus of population from the inner city to the outlying districts within the last census period.

Assuming the new equipment now on order by the United Railroads had been available to rectify the service requirements of 1911, the future growth of the city until 1920 will require an average addition of from 40 to 50 cars per year. This is a minimum schedule that can be carried out without materially diluting the net earning capacity, as San Francisco has already the highest earning rate from its equipment of any large city in the country. From 1889 to 1896, an average of 67 cars per year was added to the system, with maximum rates of increase within the period of from 140 to 200 per year.

The only way the above increase in equipment called for may be reduced is through the more efficient use of available car-miles by improved routing and by further increase in schedule speed. The size of the car units has about reached a maximum for the streets of this city.

That the extension schedule of track and cars called for here is not unreasonable is further indicated by the fact that out of the annual budget of investment predicted, about 25% will remain up to 1920 for betterments of existing property over and above the investment in new extension and equipment.

An analysis of the purchasing power of the city with respect to its utilities shows that the underlying property valuation is increasing at a slower rate than the necessary railway investment; that is, as the 1.7 power of the increase in population, instead of the square as in the case

of earnings. At the very lowest estimate, $3 of capital must be invested for every $1 earned. Under the present bond limit, therefore, the city's ability to purchase or build is becoming more and more inadequate, thus requiring a progressive refunding basis.

The present available purchasing power of the city is approximately $51,000,000 for all purposes, including water supply. By 1930 the total railway investment required will be $62,000,000; by 1950, $123,000,000. This means that over one-third of the total bonding capacity of the city on its present 15% basis would be continually preempted for railway investment alone, assuming the city entirely free from debt.

If the city of San Francisco declines to accept the assistance of private capital in financing its utilities both for the present and the future, the conclusion cannot be evaded that a revision of the bond limit must be secured immediately in order to provide the capital necessary for preserving the normal rate of growth of the city as herein predicted.

ADVANTAGES OF OIL FUEL.

Admiral H. I. Cone, United States Navy, in a statement regarding the relative values of oil and coal for steam-raising in the navy, makes clear the following points:—

The advantages of oil as compared with coal are:—

An evaporation per pound of fuel in the ratio of about 14 to 9 (15.5 to 10) and per square foot of heating surface in about the ratio of 10 to 8 (12.5 to 10).

Fuel can be taken aboard more rapidly without manual labor and without interruption to the routine of the ship. The problem of fueling at sea is solved.

Steam for full power can be maintained as readily as for low power. A vessel burning oil is capable of runs at full speed, limited in duration only by the supply of fuel. There is no reduction in speed due to dirty fires or to difficulty in trimming coal from remote bunkers or to exhaustion of the fireroom force.

There are no cinders and the amount of smoke can be controlled.

A considerable reduction in personnel is possible.

The weight and space required for boilers are reduced, first, by the reduction in heating surface required; and, second, by the shortening of firerooms. Consequent on the reduction in heating surface is a decrease in weight and cost of boilers.

Coal and ash-handling gear is eliminated. This renders unnecessary the piercing of the hull for coal trunks and dischargers from the ash-expellers or ash-ejectors.

The stowage and handling of oil are much easier than of coal, and will result in a much cleaner ship, with consequent increase in time available for drills.

The mechanical supply of fuel to the boilers gives a prompt and delicate control of the steam supply, permitting more sudden changes in speed than with coal, which is a tactical advantage.

The nature of fuel oil permits utilization of remote portions of the ship and of constructed spaces for its stowage.

These advantages have long been recognized by the navy, and there have been experiments with liquid fuel dating back as far as 1867. All these experiments have confirmed our belief in the considerable military advantages which will accrue from its use, but until recently it has been impracticable to use it extensively on account of the uncertainty as to the adequacy of its supply and the sufficiency of its distribution among the seaports of the world.

AN EFFICIENT METHOD OF ROAD-OILING.

To spread oil on roads for a distance of twenty miles or more from the starting point, and to spread it at a heat of 200 degrees or more, would seem to be an extremely difficult undertaking, requiring a lot of apparatus and a lot of men. But by the ingenious use of a five-ton truck the road commissioners of Los Angeles county accomplish it with one man and one piece of mechanism.

The truck is fitted with a 1,000 gallon oil tank, and this tank is covered with a coating of asbestos two inches thick to retain the heat. Oil is run into the tank 350 degrees Fahrenheit. Owing to the asbestos protection and the speed the truck can make, it is possible to make a trip of 35 to 40 miles before the oil gets too cold for use.

Air pressure of 60 pounds to the square inch is maintained inside the tank by an air-compressor operated by the same mechanism used to actuate a dumping body for sand and gravel.

Heat from the motor exhaust is used to keep the oil-spreader warm, so that the stuff will not thicken and clog up there. The truck travels fifty miles a day, and the driver says that in 2,000 miles only two involuntary stops were necessary on the road—both caused by dirty gasoline stopping up the fuel line.

The largest crane in the world has just been placed into operation in a Hamburg shipyard. This crane is capable of lifting and distributing 250 tons of material over an area of 182,920 feet. It was the city of Hamburg which, in the year 1888, possessed the largest crane in the world at that time, and now it is again the Hamburg shipyard of Messrs. Blohm and Voss which is able to call the largest crane in the world its own. The development of crane building during the past twenty-five years has been enormous. Germany has taken the lead in the construction of high-capacity cranes, and has delivered the majority of the 140 giant cranes which are in existence. The Deutsche Maschinenfabrik A. G. Duisburg are the constructors of this latest giant. Only two men are required for working the crane. The driver works in a cabin arranged under the load arm of the jib. In order that the crane can be worked safely after darkness a searchlight is fitted near the driver's cabin, by means of which the load is brilliantly illuminated.

The record of trade disputes maintained by the Department of Labor shows that, as is usual at this season, the majority of the disputes occurred pending the adjustment of new wage schedules. These were nearly all of short duration. The mining industry on Vancouver Island was seriously interfered with, more than 3,000 men being out during the whole month through the continuance of the dispute at Ladysmith and the Cumberland mines, and the closing down of the mines in the Nanaimo district. A great number of the disputes of the month occurred among workers in the metal trades. The disputes of May affected upwards of 11,500 employees and accounted for the loss of more than 150,000 working days. Disputes affecting the various classes of municipal employees in Vancouver and affecting also the boot and shoe workers in a number of factories in Quebec were satisfactorily adjusted during the month through the instrumentality of boards under the Industrial Disputes Investigation Act. The Department of Labor also assisted in the adjustment of disputes affecting the employees of the Hydro-Electric Commission in Toronto, and affecting also the longshoremen in Montreal and St. John, N.B. In the latter case a board has been established under the Industrial Disputes Investigation Act.

FAIR-WAGE CLAUSES IN GOVERNMENT CONTRACTS.

It has been the policy of the Government of Saskatchewan to include in all its contracts a fair-wage schedule. The procedure has met with such favor that workmen of the province are agitating the adoption of such a policy in connection with all contracts entered into by cities and towns for civic improvement. The clauses which appear in the government contracts as directly bearing upon this question are as follows:—

1. The contractor shall employ none but skilled Canadian workmen and their apprentices, and shall not pay less than the current rate of wages in the district where the work is being done, and if there is no current rate, then a fair and reasonable rate. In the event of a dispute arising as to what is the current or a fair and reasonable rate, it shall be determined by the fair-wage officer of the government, whose decision shall be final.

2. Contractors shall post in a conspicuous place on public works under construction the schedule of wages, or the fair-wage clause in their contracts for the protection of the workmen employed.

3. Contractors shall keep a record of payments made to workmen in their employ, the books or documents containing such record shall be open for inspection by the fair-wage officer of the government, at any time it may seem expedient to the minister to have same inspected.

In contracts that are to be carried out in cities and towns a schedule is inserted, setting forth the minimum rate of pay and hours of the various trades and crafts to be employed on the contract. The schedule is based on the current rate of wages for each particular craft in the locality, and is obtained through the courtesy of the contractors and the labor unions interested, and in each case the current wage which is most generally paid is accepted.

The government naturally has control over the rates of wages only on works undertaken by itself or aided by provincial funds; nevertheless, the fact that all contractors on such works must pay a fair and reasonable rate of wages has had the effect of establishing a living wage throughout the province and one that is generally accepted by contractors. On private works the government has no control over the rates of wages to be paid. It has, however, power to enact such legislation as will guarantee to the employee his wages by giving him a preferred lien on the work on which he has been engaged and making the collection of wages from delinquent employers an easy and inexpensive proceedure.

WATER vs. RAIL TRANSPORTATION RATES.

Canals have cost Canada $103,400,589. The annual interest charge, reckoned at 3½% would be $3,619,021. In 1912 the cost of maintenance was $1,725,738, making a total of $5,344,759. This means a government contribution of 76.99 cents per ton on the whole Canadian freight tonnage of 1912, or .140 cent per ton mile. Adding to these amounts the actual freight rates, viz., 91.04 cents per ton, or .194 cent per ton mile, gives a total of $11.68 per ton, or .334 cent per ton per mile.

Mr. J. L. Payne, Controller of Statisties, Ottawa, makes the following comparison between rail and water rates, basing his remarks upon the transportation of

wheat between Fort William and Montreal, via both routes.

The average rate on waterborne wheat between these points in 1912 was 5.774 cents per bushel, of $1.92 per ton. To this should be added the contribution by government of .140 cent per ton per mile, equal to $1.72 per ton, making the total $3.64 per ton. The rail rate of the Canadian Pacific Railway between Fort William and Montreal is uniformly $4 per ton, or .402 cent per ton per mile. The average rail rate of all the railways of the West on wheat is not higher. On a longer haul, say, from Winnipeg to St. John, New Brunswick, it is even lower; so that the comparison is fair. Thus, we have on this statement of facts a water rate of $3.64 per ton as compared with a rate of $4 per ton by rail. That comparison, however, is based on an average water rate on wheat of 5.774 cents per bushel. The maximum water rate for the season of 1912 between the same points was 8 cents per bushel, and at that rate the charges by water were 29 cents per ton higher than were the current charges by rail. A fair conclusion is that, on the whole, the water rate paid by the shipper is lower on certain commodities which are peculiarly suitable for transportation in steamers; but there is not a material difference between water and rail rates when all the facts and conditions are taken into account. The difference in favor of the water rate is created wholly by the fact that a considerable part of the actual cost of transportation by water is paid by the people at large.

EDITORIAL COMMENT.

Notable among the week's proceedings of engineering interest is the government call for tenders, for the Toronto harbor development, the plans and specifications for which are now complete. They pertain to seawall, breakwater, ship canal, turning-basin, retaining walls, etc. The seawall is to be 17,295 feet in length—over 3¼ miles—and is to be built in eleven sections. The structure will be of sheet piling and timber with a superstructure of concrete. The breakwater will be 18,600 feet in length and will be of timber crib work and concrete superstructure. The ship channel and turning-basin will be approximately 16,705 feet long and the whole area will be dredged to a depth of 24 feet. The retaining wall will be 6,894 feet in length.

* * * *

Ottawa and vicinity are interested in the expropriation proceedings recently instituted by the Ontario Hydro-Electric Power Commission in connection with the water-power rights at Chats Falls, on the Ottawa River, some thirty miles west of the city. A private company holds the present power rights by government lease granted two years ago. The price of relinquishment asked by them is some seven times the amount offered by the Ontario Government. The Ontario Railway and Municipal Board has the case before it, and evidence will be heard in September.

It is the intention of the Commission to use the power at Chats Falls as an Ottawa Valley and Eastern Ontario extension of the provincial system, over 100,000 horse-power being available for development in the district.

LETTERS TO THE EDITOR.

An Association for Municipal Engineers.

Sir,—Mr. R. O. Wynne-Roberts' letter in your issue of the 15th inst., has spoken the mind of many municipal engineers now engaged in the Dominion, and he evidently speaks from a knowledge of inter-communication between engineers, as I can trace his name through many English engineering associations.

Your editorial, sir, conveys a suggestion with reference to the Canadian Society of Civil Engineers, and one that every trained municipal engineer welcomes, the more so that he would be enabled to join an established and recognized community of engineers whose branches reach far out in the engineering world, and who possess amongst its members the eminent engineers of Canada.

The Dominion is developing rapidly, townships are springing up like mushrooms and the demand for public utilities in water, sewerage and roads, electric lighting and power, etc., and every other necessity for public health is being asserted in no unmistakable manner, that the time has come when none but the qualified theoretical and practically trained man can be looked upon as the successful candidate, and the competition for the appointments should lie amongst such men.

This branch of engineering is so important to the public well-being, both financially and administratively, that some steps should be taken to have it set upon a better recognized basis. Its members are men with Canadian experience, geological and climatic, whose training has been conducted upon sound scientific and practical lines, and whose experience has been gained by constant and businesslike study.

The question of the establishment of such an association or institution is surrounded with difficulties which can be overcome the more easily by subdivision. I mean that the Dominion is so extensive that the ordinary salaried engineer cannot afford to travel from coast to coast each year to attend conferences. This can be met, I suggest, by a central body representative of the provinces, whose labors shall be directed by the provincial branches; these branches, for economy's sake, to hold their meetings at various cities within their province.

If the institution could become a recognized body by the government by charter, it would materially increase its value and importance, and the aid which would be rendered from government engineering officials would add prestige to its personnel.

Under such conditions it would be a matter of easy negotiation to put forth legislation in favor of municipalities bearing the costs of their engineer's attendance at conferences throughout the Dominion, within reason, of course, i.e., an annual meeting of three to six days' period.

The status of the individual as a member should be taken care of, and various degrees of membership established—say, for a period of one year from the date of formation, chief municipal engineers would be admitted as full members, chief assistants and assistants of eight years' experience as associate members, and younger members of engineering municipal staffs as graduates.

After the first year has expired, examinations for entry as graduates or students on the one hand, and for associate members on the other, should be established. Of course, the latter examination would qualify the associate member for full membership upon his obtaining a town or city engineership.

There is an immense amount of labor to be wrought in the successful launching of such an institution, but I have no fear of its issue if the determination of the engineer is turned to it in the same spirit that he tackles the problems of his district, overcoming many of nature's obstacles, and often harnessing them for the benefit of mankind.

PRO BONO PUBLICO.

Winnipeg, July 21st, 1913.

* * * *

Concerning Toronto's Filtration Plant Extension.

Sir,—In view of the City Council's decision to spend $1,000,000 for a filtration plant at the Island, in order to avoid an expenditure of perhaps $2,000,000 for a new intake or tunnel which the placing of the addition on the mainland would entail, we would like an interesting proposal, which we have made, to appear in the columns of your journal.

It should be pointed out that it has only been made after two years' study of the existing conditions, and after a careful perusal of the various reports published, including that recently issued by Commissioner of Works Harris, Drs. Hastings and Nasmith, appearing on page 184 of July 17th issue of *The Canadian Engineer*. We would make reference particularly to several of the closing paragraphs of this report in which Garrison Common is mentioned as an ideal location for the installation of a mechanical filtration plant; but that the sum that has already been invested in the Island plant necessitated the retention of its use; also the reference to the formation of the Island being such as to render it an undesirable location for permanent construction of this nature, and the very extensive operations, which the Harbor Commissioners purpose undertaking, being liable to imperil the present or any future installation which might be established there. The continuity of a filtered water supply for 365 days per year is stated to be the dominant factor in the consideration of the proposition.

These sections of the report lead one to believe that, if the Island is undesirable for the present $800,000 construction, it will be much more undesirable for a $1,800,000 investment, considering the sand formation and the indefiniteness of the Harbor Commissioners' future operations conflicting with it. Further, the ideal site for the filter plant being on the mainland, it appears to the writer that the present filtration plant might well be retained in connection with the city water supply for use as a basin to effect settlement of the water before filtration, thus removing the troublesome sand problem which must be contended with. The new filter plant could then be installed adjoining the main pumping station, and the raw water filtered after being drawn through the tunnel, thus eliminating a constant source of danger to the pure water supply, viz., the passage of water through the tunnel under the polluted waters of the Bay. Such a plant could be located on the vacant land owned by the city between the present pumping station and the railroad tracks to the north, convenient to the mechanical operators of the former, and in a position entailing a minimum of cost for the transportation of stores and supplies.

The proposal which was recently submitted by the Bell Filtration Company covers the installation of a filter plant of 65,000,000 gallons minimum, and 96,000,000 gallons maximum capacity upon the above-mentioned site, to be installed without delay and to be in operation in about fifteen months. Without going into details of equipment, etc., it might be stated that under the proposed method the water would be first settled by the Island basins, would flow by gravity to the main pumping station, and would then be pumped directly through the filters to the city mains.

The chief advantages attendant upon this scheme are those of insurance against interrupted operation, such as might be occasioned by alterations to the Island, and the safe-guarding of the supply against dangers of pollution by Bay water.

In the event of any change being desirable at any time, the whole of this plant can be removed practically without interruption, thus increasing the value of it as an asset to the city.

H. W. COWAN.

Toronto, July 23rd, 1913.

A REMARKABLE PAVEMENT TEST.

Bereft of its concrete base and of the roadway itself, something like 100 square yards of brick pavement on Dunham Road, near Cleveland, are projecting over the void with nothing to hold them in position but an excellent job of cement grouting between the bricks themselves.

This spectacular test of Cuyahoga County's road-building methods came to pass through the agency of a recent freshet in Tinker's Creek, a small stream skirting the road. Retaining wall 275 feet in length was swept away and the earth undermined for nearly 100 feet. The concrete base was next to go, leaving the brick bare for a distance of 80 feet. The greatest breadth of the brick overhang is seven feet.

Washout Under a 14-Foot Brick Road in Ohio.

So solid was the course of grouted brick that it was a job of no small difficulty to remove two bricks in order to erect posts for a warning fence. After the holes had been made, the engineer in charge did not hesitate to drive his auto upon the overhang and pose beneath it. At first it was planned to break the pavement down and rebuild it after the road had been filled, but the solidarity of the structure has brought about an alteration of plans and now county engineers actually contemplate building the road up to the pavement without disturbing the latter.

Cuyahoga County has over 400 miles of rural brick highway, counting the 50 miles to be installed during the current year. Macadam was long ago abandoned as unsuited to the heavy and growing automobile traffic. The construction of a heavy, solid base and utmost care in the application of a cement grout filler have been the keynotes of successful road construction in Cuyahoga County.

PREVENTION OF LANDSLIDES IN CONSTRUCTION WORK.

By Geo. S. Rice.
Chief Mining Engineer, U.S. Bureau of Mines, Pittsburg, Pa.

THE slides in the Culebra Cut which have so severely handicapped operations on the Panama Canal construction, and the likelihood of them continuing to occur, as such a conclusion may be arrived at from a perusal of the report for 1912 of the Isthmian Canal Commission, suggests the advisability of preventive measures, as far as the geological formation of the isthmus will permit. Mr. Rice suggests the utilization of a process used in shaft sinking and tunnel work—that of erecting an underground retaining wall which would have a tendency to prevent the formation of a slide by taking care of the unbalanced pressures due to deep excavation. His suggestion forms the basis of a paper read before the Western Society of Engineers, Chicago, on May 12th, from which the following abstract is made:—

While the method of filling cavities and rock crevices behind tunnel lining with cement grout has long been employed, a special application called the cementation process has been highly developed in France for sinking through porous and creviced water-bearing strata. Briefly, it consists of drilling a series of holes surrounding the shaft location through the porous strata to the more of less impervious coal measures, and pumping in cement grout under high pressure. The pumping may be either continuous, as the drilling proceeds, or (as in later undertakings was found to be better) in stages at intervals alternating with drilling every 16 ft. By this method a cylinder of cemented material is constructed within which the shaft can be sunk. In the earlier undertakings four drill holes were used, but for later shaft sinkings six holes were employed in a circle of 24 ft. diameter.

To prevent leakage to the surface of the injected grouting, a pit is first dug for each bore-hole through the loose earth and concrete placed tightly about a 12-in. standpipe, the top of which is capped. The cap has a stuffing-box, through which passes a grouting pipe that can be pushed to near the bottom of the hole. The pipe is connected with the pump, and the latter with the cement mixer. Before injection of cement begins, clear water is pumped through.

It has been found necessary to use only the finest ground cement, and employ pressures as high as 750 lb. per sq. in. to insure the thorough permeation of the cement into the small crevices and bedding planes of the strata. The cleaning out of all mud coating on the bore-hole is also found necessary. To this end it is the practice to drill the hole below the standpipe, about 7 in. diameter, and then ream to 10 in.

The water-bearing strata consists of marls or fissured chalks which are sometimes argillaceous. They are soft enough to be bored with an auger drill turned by power. The process has been so successful that it is supplanting the freezing system for sinking through highly water-bearing strata in northern France and Belgium.

Constructing Underground Retaining Walls.—The success achieved with the above process appears to offer possibilities in solidifying the slopes of unstable strata, at least sufficiently to prevent movement from occurring. The holes filled with concrete, reinforced with iron bars, would serve as deep-seated massive piles. Why not extend this principle and drill inclined holes to solid strata, and insert in them heavy reinforcing bars which, when surrounded with cement, would act as diagonals or tension members?

A further development was to "spring" the holes at the bottom by shooting with dynamite. This would open up crevices, permitting a more extensive cementation, and would provide an enlargement which would furnish anchorage for the tie bars. The upper end of the tie bar is to be held by a concrete capping. Thus the combination of vertical concrete posts and inclined metal ties (going deep enough to reach solid strata), with the ground cemented between, would furnish a triangular dam, or retaining wall, which should have great strength against lateral pressure.

The nearer the holes, the more thorough would be the cementation. The only limit would be that of cost. The system, if applied extensively, would be costly. But it would only be considered where the cost of repairing damage to an engineering work by an extensive landslide would be vastly greater.

In proposing the scheme for checking, or rather preventing slides, the writer has had three main thoughts in mind: 1, as far as possible there should be drainage; 2, there should be a subdivision of the slopes from which the slides are liable to come; 3, there should be formed an underground dam, to prevent the foot of a slope from moving, and also to keep the water of the canal from circulating through the material. It is very much more destructive to the somewhat soluble walls to have water constantly entering and leaving the crevices through wave action, than if the ground water is merely held quiescent.

The scheme is as follows:—

1. To drill a series of holes along lines parallel with the axis of the canal, these holes to be both vertical and inclined, and go deep enough to reach firm strata below the level of the bottom of the canal. The depth of the holes might need to be 100 ft. or over 150 ft.

2. Cement grout to be forced into these holes under pressures of 750 to 1,000 lb. per sq. in., so that the cement will penetrate all the fissures, making the mass impervious to water, and also binding the rock together.

3. Steel rods, 3 in. diameter or more, to be grouted into the holes.

4. Before the steel bars have been placed, dynamite is to be fired in the bottom of each hole to make an enlarged space in the firm stratum which the holes should reach. These will provide anchorage at the bottom. The rods will thus act as reinforcement to the cemented zone; and the rods in the inclined holes will serve as tension members of the wall. The latter rods will therefore be made much heavier than the others. The rods are to have nuts and washers or to be upset at each end. The upper ends are to be fastened in a concrete capping over the top of the "dam."

This method cannot be applied to ground that has begun to move. It cannot be applied to ground that is actually moving. Moreover, the wall must go sufficiently deep to get into solid strata. But there is nothing except cost to prevent such an underground dam from going as deep as seems desirable, or to make the holes as large or the tie rods as heavy as desired. It would be desirable to try the method beyond the present slide areas in order to determine the obstacles and necessities of the case. The work could be pushed from either edge into the slide area. Intermediate ground walls could be constructed further up the slopes, so as to lessen the weight

and also to prevent water which might enter above from working down into the larger mass below. Accompanying these dams, underground horizontal drifts might in some cases be put into the slopes to drain the ground.

THE CONSULTING ENGINEER AND THE MUNICIPAL ENGINEER.

By H. C. H. Shenton.

THERE should be no antagonism between the consulting engineer and the municipal engineer. They are both members of the same profession, and for that reason should carefully study their common interest. Signs are not wanting that the time is ripe for combination among engineers with the object of improving their standing and general welfare, and a paper read by Mr. Shenton before a meeting of the Institute of Municipal Engineers in London, on June 25th last, has for its object the furthering of such co-operation.

There is absolutely no difference in status between the two branches of the profession. We are all engineers, we all start level, we all receive much the same education and training, and eventually elect to specialize or to take up municipal appointments, or work in some other branch of the profession not under present consideration. Without doubt, a great municipal engineer of long experience is a better man professionally than a consulting engineer of smaller experience, and similarly a great consulting engineer is professionally of more importance than a municipal engineer of lesser attainments. This may be a truism, but it needs to be understood properly in order that, when they have to work together, the senior man (as regards experience and attainments) should take the lead without any feeling on the part of his friend, the consultant or salaried official, as the case may be, that he is being treated with want of proper consideration.

The Engineer's Qualifications.—The combination of all classes of engineers into one body is not beyond hope, but the combination of engineers of a particular class should not only be quite possible, but may well be attempted at the present time. For instance, all engineers holding municipal appointments could combine very easily, but in the author's opinion such combination would be incomplete, because it would leave out a very large number of men who advise as to the construction of some of the most important works of local authorities—viz., the consulting engineers. A difficulty at once presents itself as to who should be included in such an organization and who should be excluded. It is not to be denied that there is a certain number of consulting engineers whose experience does not entitle them to call themselves "specialists," and whose knowledge of the subjects upon which they undertake to give advice is inferior to that of the average municipal engineer; persons whose knowledge on all matters not pertaining to municipal work may or may not be great, but who are looked upon with considerable disfavor, and justly so, by those municipal engineers with whom they may have to work. Any man, however limited his knowledge may be, is at the present time able to write the letters C.E. after his name, take an office and give advice, and if he possesses influential friends and a plausible manner he stands a good chance of obtaining work with which he is quite unqualified to deal. There ought to be some method whereby such persons should be prevented from advising as to the spending of public money. On the other hand (and it is necessary to be perfectly frank) there are many persons holding positions in municipal or district council offices who by no stretch of imagination can be considered worthy of the title of "Engineer." In the author's opinion a district surveyor is, or should be, an engineer; yet in small urban and rural districts, and even perhaps in some boroughs, where the salaries paid to the district surveyors are too small to tempt experienced men to act, men of a very inferior type as regards experience are frequently employed. Ignorant councillors are frequently of opinion that if a man is a good bricklayer or tradesman he is an engineer, and they employ him as their surveyor partly from motives of mistaken economy, and largely because they prefer to have someone to whom they can dictate, and whom they will treat with very little respect, thinking that thereby they, being omniscient in all matters pertaining to the surveyor's department, may have the ruling hand. In this way the dignity of the engineer's position is lowered, and an enormous waste of public money takes place.

The properly trained and qualified man, whether he is a municipal of a consulting engineer, looks with considerable dislike on the two classes of amateur engineer mentioned, and he would like to see the profession so organized that the incompetent person should find it as difficult to call himself an engineer as to call himself a lawyer or a doctor. However, on this point one must carefully avoid coming to a false conclusion. There are many good engineers whose early training was that of a different calling, but who possessed such ability that they forced themselves forward, gaining experience, it may be, in a very humble station, and finally taking their places in the profession as honored members with absolute justice. It is therefore necessary to consider whether many of the men who cause so much annoyance by undertaking work for which they can show no proper qualifications, and by doing it for an entirely insufficient remuneration, are not often persons of considerable ability whom it would be difficult and unwise to treat as being completely outside our ranks. The very fact that they possess the assurance to undertake engineering work suggests the possession of one of the qualities most necessary to all engineers—viz., pluck. These men, whatever their previous condition may have been, may be quite capable of gaining the necessary experience and training to qualify them as engineers, but till they have done so, whatever their age and position may be, they can only be regarded as juniors, and should be treated accordingly. In that case the local authority who tried to employ such unqualified persons in chief positions, or as consultants, should be prevented in the same way as they could be prevented from appointing a medical student to the position of medical officer. Leaving out of our consideration the inexperienced class of men on both sides, we may consider the remainder as belonging to one class, and these ought to be able to unite for their common good.

The Engineer's Remuneration.—The most important question at the present time is that of remuneration. No engineer ought to be made to work for insufficient payment. The municipal engineer is sometimes a perfectly competent specialist, and can advise his council better than any consultant upon a given matter outside his ordinary duties, but when he does so without receiving proper fees such as the consultant would charge he is doing the profession serious harm. He is ranking himself with a sort of consultant who prepares schemes for

nothing, or who obtains work by offering to do it at a reduced commission. In the abstract one must condemn such practices utterly, but such is the unfortunate condition of the profession, owing, however, entirely to lack of organization, that the municipal engineer may be forced to do work quite outside his ordinary duties without charge, in order to keep his position, and the consultant may be forced to work for nothing in the hope of being able to make a living some day. This is entirely wrong, but it has been done. There is only one remedy: we, as engineers, should combine and organize for registration, so that the incompetent men may be excluded from the ranks of those who act in chief positions, and when this has been done we shall be able to refuse to work except to a proper scale of charges; and, moreover, we ought to be prevented from doing so. Means must be devised whereby it is made impossible for local authorities to obtain the services of their salaried officials or of consultants except by paying proper salaries or proper fees. In this matter the assistance of the Local Government Board is required, and it is not beyond hope that such assistance would be given if once the profession were properly organized. It is perfectly clear that the board have the greatest dislike to the employment of unsuitable persons by local authorities, and that even at the present time, as far as their powers permit them, they do very good work in refusing to sanction loans for unsuitable schemes prepared by incompetent persons.

It is urged at times that the municipal engineer is unfairly taking up the work of the consultant. This, in the author's opinion, is quite incorrect, for it is obviously the bounden duty of a municipal engineer to give his best services to his employers, and so long as he can do the work, and his remuneration is adequate, the consulting engineer has no grounds for complaint. Where a consultant is called in to advise a local authority, his work should be done in such a way as to assist and strengthen the position of the municipal engineer, and similarly the municipal engineer should work with the consultant so as to ensure the success of his work in every possible way, both sides avoiding doing anything likely to bring the profession into disrepute. In the author's experience these relations are generally quite satisfactory, but it would be of considerable interest to learn the experience of others upon this point.

A consulting engineer is sometimes called in by an authority whose surveyor is a man of knowledge and experience, but whose services are entirely undervalued and underpaid by his council, and whose position is the reverse of pleasant. It is possible in such a case for the consultant to insist upon proper respect being paid to such a man, and he should make it his business to do so and to help him to advancement in every way possible, as the council are likely to attach importance to the action of the consultant and to the degree of respect with which he treats the surveyor.

It may be asked whether it is possible, after all, to make an exact distinction between the man who is an engineer and the man who is not? In the author's opinion there is no difficulty whatever in deciding whether a man is a qualified municipal engineer. It is not at the present time a question of examinations passed, of pupilage, or of membership of societies and institutions. It is simply and solely a matter of training and experience, and unless a man has been occupied for an extended period on municipal engineering work he cannot by any possibility be rightly called a municipal engineer. A civil engineer is not necessarily a municipal engineer any more than a doctor is necessarily a medical officer. Similarly with regard to consultants the consulting engineer is a specialist, and this implies that he has made a special and extended study of some particular branch of engineering, such as waterworks, sewerage, or electrical work. He is an expert in some particular work, and it is obvious that he is sailing under false colors if he calls himself an expert unless his knowledge and experience of the particular work he undertakes are extensive. It is very desirable that engineers in private practice who undertake to do work upon which public money is spent should be carefully registered, not simply as engineers, for that term is too vague, but as water engineers, gas engineers, sewerage engineers, tramway engineers, etc., as the case may be. It is, after all, a simple matter for a man who poses, say, as a gas engineer, to show that his experience is such as to qualify him to give advice on that subject; if he cannot he is not fit to advise as to the spending of public money on gasworks. Municipal engineers can help their consulting brethren on this point greatly by urging their authorities to see that their consultants on any particular work are really specialists for that work, and not for something else. They can also assist very materially by joining energetically as a body in any scheme for combination which may be forthcoming for the better organization of the profession.

Points for Discussion.—(1) The proper qualifications of the municipal engineer.

(2) The proper qualifications of the consulting engineer.

(3) How to prevent local authorities from employing: (*a*) Incompetent persons in municipal engineers' positions: (*b*) Incompetent persons as consulting engineers.

(4) The inclusion or exclusion on municipal work of persons whose training and experience is insufficient to qualify them as engineers. Should these persons be considered as juniors qualifying for the position of engineer, or how should they be regarded?

(5) The position of the municipal engineer who is doing consulting work without receiving proper payment.

(6) The position of the consulting engineer who works without receiving proper payment.

(7) The ways in which the consulting engineer and the municipal engineer may help each other.

(8) The better remuneration of municipal engineers, and the combination of both classes of engineers for the improvement of their profession.

The area of the Forest Reserves in the Union of South Africa in December, 1911, was 1,799,550 acres. Besides this, there were also 42,587 acres reserved for growing railway ties, on which railway funds alone were expended, making a total reserved area of 1,842,137 acres. Forest surveys are being made for the demarcation of new reserves, and existing reserves are being protected from fire by burning or cutting fire-belts around the reserves and by planting up their perimeters with trees of the less inflammable species. As a result of these precautions there were burned during the season of 1911 only seven hundred acres, or 0.04 per cent. of the total area.

The fourth International Road Congress will be held at Munich in 1916, as a result of an invitation from the Imperial German Government, seconded by a representative of the Bavarian Government.

THE ROD AND MERCHANT MILLS OF THE DOMINION IRON AND STEEL COMPANY, LIMITED.

Believing that all readers of *The Canadian Engineer* are interested in the progress and development of the Dominion Steel Corporation, now the largest metallurgical enterprise in Canada, we have arranged for a series of descriptive articles, each one of which will be devoted to some particular unit or group of units that goes to make up the complete plant, which now includes facilities and appliances of the most modern description for all purposes, from the winning of coal and ore to the manufacture of quite highly developed forms of steel products.

Instead of taking these in the sequence of the processes to which they relate or of the time of their installation, we propose to take some of the newer items first, grouping with them some of the earlier parts of the plant which are closely related to them.

The plan which accompanies this article shows the layout of the Steel Company's rod and merchant mills. The rod mill was built in the year of 1904, has since been in practically continuous operation, has turned out over half a million tons of rods, and has incidentally made what are believed to be world's records for production for a day, a month and a year.

This mill is of the type known as the Morgan continuous rod mill. The roll trains consist of six stands of 12-inch roughing rolls and eight stands of 10-inch finishing rolls. The roughing train is driven directly from the engine by a system of pinions geared to the main shaft. The finishing train is driven by a pair of 48-inch double belts from a 22-foot flywheel. The engine was built by Ehrhardt & Sehmer, and is compound condensing, with cylinders of 35½-inch and 59-inch by 51¼-inch stroke.

The rods are delivered from the finishing mills through tubes to four reels, upon which they are coiled hot. From these reels they are dropped upon a flat, motor-driven bundle conveyer inclining upwards from the point where it receives the coils, below the main floor level, to the end of the bundle conveyer, about 150 feet distant. Here they are transferred to the bundle-cooling carrier, which conveys them about 375 feet to the bundling shed. By the time this is reached the rods are cool enough to handle and are tied up for shipment.

Rods of all sizes, from No. 5 wire gauge to ⅜-inch in diameter, are rolled in this mill.

The billets used are 30 feet long by 1¾ inches square, made in the company's billet mill, which will be described in another article.

Parallel with the rod mill is the new merchant mill, which is not only the latest of the finishing units to be put in, but is also from the very latest designs of the Morgan Construction Company, of Worcester, Mass., who constructed both mills. It consists of one train of six 12-inch continuous roughing stands and three Belgian trains of two stands each, one with a pair of 9½-inch and the other with a pair of 10½-inch rolls.

The roughing mill is equipped with feed-rolls, emergency shear, etc., and is driven by a system of pinions geared direct to a 36-inch by 48-inch simple engine.

The finishing mill is driven by two 52-inch double belts from the flywheel of a 24-inch by 48-inch twin simple engine.

Both engines were built by the Robb Engineering Company, Limited, of Amherst, N.S., and are of the piston valve type, designed to run at speeds varying from 60 to 100 R.P.M., and are fitted with Schutte-Koerting engine safety stop valves.

The finishing mill is equipped with automatic repeaters on the delivery side, emergency shears, etc., and is arranged to deliver either to a cooling bed or to pouring reels.

The pouring reels are similar to those used on the rod mill, but can take squares up to ¾ inch and rounds up to ⅞ inch. They deliver the coils to a motor-driven, flat bundle conveyer 100 feet long. This is beneath the floor, and passes diagonally across the mill and inclines upward to the bundle cooling hook carrier, which is driven from the same motor, and automatically picks up the bundles and conveys them 554 feet to the bundling shed. The bundle carrier has a capacity of 88 bundles, and speed can be varied to suit the stock, giving ample time for it to cool thoroughly by the time it reaches the coil-bundling shed, from which it is shipped. Part of the smaller rods, which are made into wire or nails, is transferred by a second bundle carrier to the cleaning department of the wire mill, which will be described later in an article upon the wire and nail mills. These conveyers are much the same design as those in the rod mill.

The cooling-bed is the Edwards inclined mechanical escapement type, with a capacity for eighteen pieces 360 feet long. The pieces are conveyed to the upper side of the cooling-bed on a cone roller conveyer, and are delivered to the shear by a roller table conveyer on the lower side. Both conveyers extend the full length of the bed. The pieces can be cut to any length. After shearing the pieces are pushed by a steam kick-off to the scale, which is beside the shear-table, and is provided with suitable cradles to hold the bars.

The shear is vertical, motor-driven, and has a capacity of fifteen bars ¾-inch in diameter, or their equivalent.

The whole mill floor is commanded by an 85-foot electric overhead travelling crane of fifteen tons' capacity. This is used for all the purposes of the mill, including the carrying of finished stock from scales to bundling floor or to cars for shipment. Among the other accessories of this mill are a five-spindle motor-driven bar-twister, built in the company's shops, and a motor-driven shear for cutting cold bars from stock. A standard gauge railway track extends about 400 feet into the mill building, upon which cars are run in for loading direct from the stock floor.

Billets used are either 1¾ inches square or 2½ inches square, according to weight of bars or other sections to be produced, and are all 30 feet long.

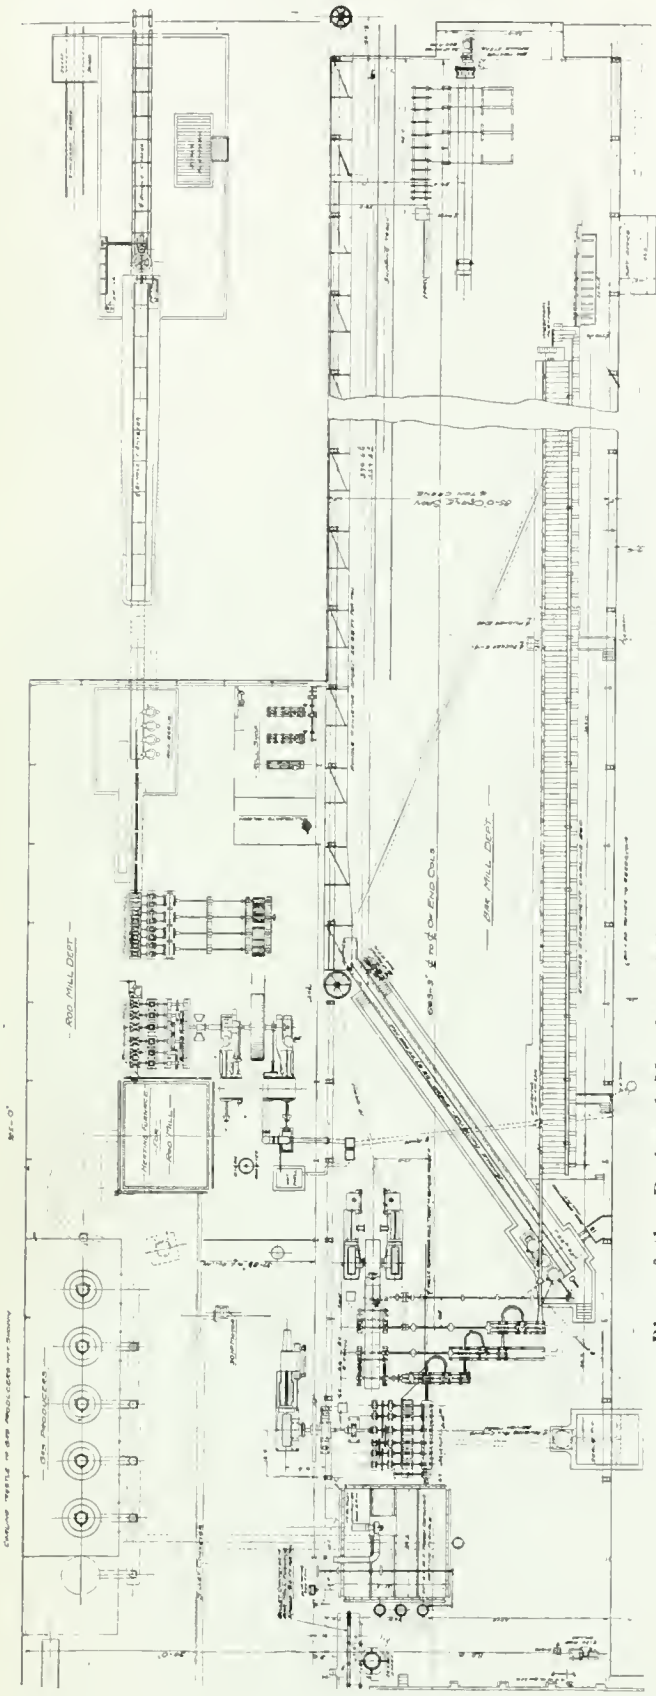
The output of the mill may be in a variety of forms. Coiled squares or rounds can be finished from ¼-inch to ⅞-inch, or the equivalent. Round and square bars from ¼-inch to 1½-inch can be finished, straightened and cut to any length. Flat bars can be made from ½-inch by ⅛-inch up to 3 inch by ½ inch, as well as the equivalent of this range of sizes in half-round, oval or special shapes of various sections. It is well adapted for rolling angles up to 2 inches by 2 inches by ⅜ inch and channels up to 3 inches.

Each of these mills is provided with a continuous gas-fired heating furnace of the Morgan suspension roof type, with a working hearth 32 feet wide and long enough to take 90 2½-inch or 162 1¾-inch billets. Both furnaces are supplied with gas from Morgan automatic gas producers, of which there are five connected up in one battery. Coal is delivered direct to the charging floor from cars placed upon an elevated trestle parallel with the producer building and connected with the main track system.

Billets for use in these mills are stored in a yard adjoining the end of the mill buildings, and served by an overhead travelling crane 36 feet span, with runway 325 feet long. The bridge and trolley are motor-driven, and lift and carry ten billets at once. From this yard they are transferred by motor-driven roller conveyers to the heating furnaces.

The roll-turning department is conveniently located in the south-west corner of the rod mill building, and serves both the rod mill and bar mill. Steam for the mill engines is provided principally from a newly-constructed boiler plant provided with automatic stokers, chain grates, etc. A full description of these will be given in an article upon the

power system. Mill-cooling water is impounded in a cooling reservoir, the return water flowing in an open flume arranged with baffles, and is repumped to the mills. This will be described in a later article under Water System.



Plan of the Rod and Merchant Mills of the Dominion Iron and Steel Company.

Fresh water is used on the furnace coolers, this being sufficient to act as a make-up for the losses due to evaporation and leakage. Great care was exercised in designing the waste water conduits beneath the rolls to make them self-cleaning. All the scale is carried to the scale-pit and deposited in a self-draining scale-box, which is lifted by crane and discharged to cars. The overflow water from the scale-pit returns to the cooling reservoir.

Small scrap is balled in a scrap-balling machine, while cobbles and the larger scrap is sheared up and all loaded direct into charging boxes in readiness for use in the open-hearth furnaces.

The buildings in which these mills are housed are of standard steel construction. The rod mill building is 90 feet span by 325 feet long, and the merchant mill building 88 feet 6 inches span by 663 feet 3 inches long. The side walls of the rod mill building are covered with reinforced concrete. The side walls of the merchant mill building and the roofs of both buildings are covered with corrugated galvanized iron. Both are well provided with light, especially the merchant mill, which has continuous windows 10 feet wide of heavy wired glass extending full length of the building, and set high up in the wall so as to give the maximum of light with the minimum of breakage.

KAMINISTIQUIA POWER COMPANY

The decision of the Kaministiquia Power Company to carry out further extensions to its plant at Fort William, thus increasing its power capacity is another evidence of the unusually active growth which is taking place in the advantageously-located twin cities of Fort William and Port Arthur.

The Kaministiquia Power Company was incorporated in 1905, when it purchased from the Ontario Government the Kababeka Falls on the Kaministiquia River, 18 miles from Port Arthur and Fort William, Ont., and immediately commenced the development of this water power. The initial development was completed in December, 1906, and subsequently has been added to. There are now installed three electrical units of 3,750 kilowatts, each making a total equivalent to about 15,000 horsepower. The hydraulic development may possibly have been made in three units, of about 7,000 horsepower each.

The present hydraulic development is equal to a round 20,000 horsepower, of which there was added in 1911, one unit of 7,000 horsepower capacity in turbines, generators, etc., and the extension was made to the power house to accommodate this extra equipment.

It will be seen, therefore, that at the present time the company has a hydraulic development with a capacity of 20,000 horsepower and plant and machinery installed with a capacity of 15,000 horsepower. It is the intention to proceed with a hydro-development of 10,000 additional horsepower, making a total development of 30,000 horsepower. At the same time it will install an additional unit of electrical machinery with a capacity of 15,000 horsepower, thus doubling the present electrical capacity and making a total of 30,000. The company will thus be able to take advantage of the entire power at its disposal. It is said that the undertaking will involve an additional expenditure of about $1,000,000. It is the intention to begin work in the immediate future and it is expected that the undertaking will be completed at the close of 1915.

The Kaministiquia Power Company is in a somewhat unusual position in this that it does not enter into competition with the Hydro-Electric Power Commission of Ontario. Instead, it supplies the power to the Commission, the Commission in turn supplying current to the city of Port Arthur for municipal and industrial purposes. The Kaministiquia Company supplies Fort William direct.

BOOK REVIEWS.

Gas Engines and Producers.—By Lionel S. Marks and Samuel S. Wyer. Publishers, American School of Correspondence, Chicago. 151+62 pages; 6 x 9 inches; illustratd. Price, $1.00.

This book is divided into Parts I. and II., dealing with gas and oil engines, and Part III., which treats of gas producers.

It will no doubt be news to many to learn that as long ago as 1678 the Abbé Hautefeuille suggested a form of internal combustion motor in which gunpowder was to be utilized; but 1860 was the earliest date at which any really practicable motor of this type was devised.

The first part of the book, following a brief historical sketch, is devoted to a description of several different makes of engines, and illustrations are given which clearly show their action.

The introduction states that this publication is "designed to present theoretical and practical information in such form as to appeal both to the engineer and to the untrained person, who is merely interested in the subject," but, from the language employed, the latter would need to have a moderate acquaintance with engines, and also of elementary physics and algebra, in order to read it intelligently and derive any benefit from it. For example, on page 25 an equation for finding the temperature of a charge of explosive mixture at the end of compression, assuming a certain initial temperature is given, in which the assumed initial temperature of 60° F., is reduced to an absolute temperature by adding 461 to the Fahrenheit reading, but no mention is made of what the quantity 461 denotes, or why it is thus added.

In the section to which the foregoing paragraph refers the book would be somewhat improved by stating clearly in a table what the various symbols P_1, P_2, P_3, V_1, V_2, V_3 etc., represent.

The arrangement followed is not particularly good. The time-worn method of dividing into chapters has been abandoned for a less effective one, and, further, the reader is jostled about from a description of types of engines and some of their parts, to theory, then to ignition and governors, followed by a section on gas-producers, which, though in the title relegated to Part III., are treated briefly in Part II., this section being obscurely located in between a description of the various kinds of gases which are utilized for power purposes and a section in which large gas engines are described.

On the first page of the "Contents" occurs a printer's error as in "Magnetic, make and break," the last word being spelled "brake."

In Part III., which, by the way, is better arranged than its predecessors, the absurdity of certain expressions which have come into rather common use is rightly pointed out. "Siemens Gas," "Dowson Gas," "Mond Gas," etc., are instanced, and these are compared with what would be perfectly analogous expressions applied to steam works. For instance, the steam generated in a Stirling boiler might, on the same principle, be called "Stirling Stam."

The illustrations throughout the book are good, clear and well chosen, while the subject matter is reliable. The question of arrangement is largely a matter of opinion after all. As a text book for a correspondence school from which students can obtain information on points which may not be quite clear it should prove to be very useful.

Logarithms for Beginners.—By C. N. Pickworth, Manchester. Published by D. Van Nostrand, New York City, and Emmott & Co., Manchester. 50 pages; 5 x 7 inches; cloth binding. Price, 30 cents net.

The author gives a detailed explanation of logarithms and their numerous applications, superior to that to be found generally in academic texts. As such the book should be welcomed. The fact that the newly published edition is the fourth speaks strongly in its favor.

The treatment is complete, with examples, exercises and answers, and with four-place tables of logs and antilogs. The chief feature of the fourth edition is a table of hyperbolic logarithms and an explanation of their use. One is again reminded that logs to base e (2.71828), called hyperbolic, or natural, logarithms, are not the Napierian logarithms, the assumption being erroneous that such logs were employed by Napier, and that, in reality, they were afterwards deduced from those invented by him.

Theory of the Flexure and Strength of Rectangular Flat Plates Applied to Reinforced Concrete Floor Slabs.—By Henry T. Eddy. Published by Rogers & Company, Minneapolis. Cloth; 6 x 9 inches; 104 pages; illustrated. Price, $5.00 net.

This treatise embodies the results of a mathematical analysis of the mushroom system of floor-slab design, invented and patented by Mr. C. A. P. Turner. Dr. Eddy, the author, has here given a rigid application of the mathematical theory of elasticity to the problem presented by multiple-way reinforcements.

In the introduction to the book Mr. Turner states that this discussion is intended as an advance chapter or two of a more comprehensive treatise on Concrete-Steel Construction, in which it is intended to treat somewhat fully concrete columns, beam and slab construction, wall panels, etc., as well as flat slabs, and to introduce the results of experimental work now under way to determine the value of Poisson's ratio for different combinations of steel and concrete. This treatise will then represent the joint efforts of a professional

mathematician accustomed to treating these problems and a professional builder and designer of reinforced concrete with many years of practical experience behind him.

Rivers and Estuaries.—By W. Henry Hunter. Published by Longmans, Green & Company, 39 Paternoster Row, London. Canadian agents, Renouf Publishing Company, Montreal. Cloth; 6 x 9½ inches; 66 pages.

This little volume, which comprises an elementary study of "Rivers and Estuaries," is to a large extent based upon lectures on this subject, which were delivered by the author in the beginning of 1911 at the desire of the Council of the Institution of Civil Engineers, and under the Vernon-Harcourt bequest, to the students of the Institution in various parts of Great Britain; and upon further lectures on the subject of "Streams and Tides," delivered in the University of Manchester to the students in the Department of Engineering there.

The treatise contains a great deal of valuable information on the behavior of rivers under natural and artificial conditions, much of which information has been compiled from the author's personal experience. Some idea of the treatment of the subject may be obtained from the headings of the various chapters, viz.: Difficulties of the Subject, Physical Difficulties, the Pursuit of Information, Flow around Bends, Mouth of the River, River Improvement Works, Some European Examples, Some American Examples, the Mersey Estuarial Models.

The book is well written in clear and simple language, and forms a valuable addition to the literature of the subject.

Electric Interlocking.—(First edition.) Published by the General Railway Signal Company, Rochester, N.Y. 435 pages; 4 x 7 inches. Price, $3, postpaid.

"Electric Interlocking" is a handbook that will be of service in switch and signal practice, containing in well-printed, well-illustrated and durably-bound form a careful treatment of electrically-operated interlocking mechanisms and appliances. The handbook contains 284 illustrations, and many tables similar to those found in ordinary handbooks. Some of its illustrations and wiring diagrams have the current-carrying wires printed in red ink, making them readily distinguishable when referred to in the text. Sections are devoted to the installation and operating data of the various appliances, to wire and conduit work, installations in concrete, including general information covering methods of mixing and tables of volumes of materials required. Various sections also are devoted to standard signals, nomenclature of units, wires, etc.

The book will prove itself generally useful to railway men, not only for the newer instruction it contains, but for its concise form for reference and its carefully compiled index, covering in detail the entire work. The index is one of the distinctive features of the handbook.

The D'Este Steam Engineers' Manual.—Published by the Julian D'Este Company, Boston, Mass. 480+54 pages; 4½ x 7 inches. Price,

The manual is in two sections, Steam and Electrics. It contains a carefully selected mathematical introduction leading to the manipulation of logarithm and of steam tables, etc. The first part then covers mechanical details, such as the heating of feed water, shafting, size of pulleys, and the like, clearly and concisely, and, although we are of the opinion that the space devoted to elementary mechanics is somewhat unnecessary to the text, still it is largely a question of opinion, and is atoned for by the admirable treatment of mechanical energy and power transmission. The handbook also contains sections relating to internal combustion engines, mechanical refrigeration briefly.

Peculiar to this latest edition, which is the second, is an electrical appendix by Charles Penrose, E.E., which occupies some 360 pages, and is entirely distinct from the steam section. It is to be pointed out that the latter comprises a valuable addition of material not contained in the first issue of the manual, but that the electrical appendix outclasses the steam section to such a degree that the title of the book as given above hardly seems applicable.

The electrical section contains 240 illustrations of electrical equipment and diagrams, and no phase of electrical work that would be of interest to steam engineers has been overlooked. The section is, on the whole, well arranged as to prove itself of value for electrical engineers as well.

One feature which the book lacks is a suitable index. That relating to the steam section is buried in the midst of the text, illustrations are not indexed at all, and the index to the electrical appendix is scant. Overlooking these deficiencies, the manual is, as stated, greatly enhanced by the additional sections, and will prove itself almost indispensable to steam engineers. An attractive feature is in the comprehensive bibliography which supplements the steam section.

The Concrete House and its Construction.—By Maurice M. Sloan. Published by the Association of American Portland Cement Manufacturers, Philadelphia. 224 pages; 6 x 9 inches; illustrated; cloth binding. Price, $1.00 net.

This book endeavors to make clear the advantages of concrete in the construction of buildings. It compares in its preface the fire losses of American and European countries, and attributes the lack of fireproof construction to a mistaken idea of cost. It goes into detail with concrete construction as applied to houses, and should be particularly valuable to the architect.

Chapter I. deals with the advantage of concrete over other materials for house construction. Architectural design is dealt with in Chapter II., and in this chapter, as well as throughout the book generally, the illustrations are for the most part new and unique, certainly displaying a wide adaptability of cement in both the interior and exterior. Details, such as types of floor construction and reinforcement, roof and wall construction, are dealt with superficially in Chapter III., which is followed by general suggestions regarding construction operation, including the laying of reinforcement, the treatment of concrete surfaces, etc. The determination of strength and design of reinforced concrete in house construction suitably well covered, little of a technical nature being attempted, only sufficient to bring out general proportions of various members as called for by the loads to which they will be subjected.

Chapter VII. contains a number of tables for use in the design of reinforced concrete construction, giving resistance moments of floor beams or slabs, etc., for various diameters of reinforcing rods and spacings. Concrete block houses are lightly dealt with in the closing chapter, included in which are a number of illustrations showing the attractive character of concrete, even in its use as plain block, no ornamentation or pretentious manner being attempted.

The book is well printed and very handsomely illustrated, and the qualities which concrete construction possesses by way of durability, sanitation, fire resistance, etc., are carefully outlined.

Electricity for the Farm and Home.—By Frank Koester, A.M.A.I.E.E. Publishers, Sturgiss & Walton Company, New York. 279 pages; 5 x 7 inches; 35 illustrations; cloth. Price, $1.00 net.

Frank Koester's books generally lend themselves to careful reading by reason of the continued interest which is created as one progresses, and his latest book is no ex-

ception. He begins by pronouncing electricity as the greatest agent of agricultural problems, of vital importance to the city dweller as to the farmer. He devotes a chapter to the idea of central station service for farms and another to the generation of electric power by water steam, internal combustion, wind, storage battery, etc., and its distribution, turning then to the subject as viewed from the application of electric motors. A chapter on costs gives in concrete form valuable information for farmers, basing his data on a farm 100 acres in size. The manufacture of farm by-products, the preservation of farm products in general and their transportation are fully treated from the standpoint of electrical power utilization. The manipulation of farm machinery and divers applications is followed by a similar treatment respecting the household, such as electric heating, lighting, etc. An interesting chapter is that concerning electric power in irrigation and pumping system, and one even more interesting is the closing chapter devoted to the stimulation of vegetation by electricity, which, although it deals only with light experimental work and contains little practical information shows an application of electricity not generally known, but highly absorbing.

The book is well illustrated, and, although a great many of the cuts are reproduced from periodicals, the choice is very creditable.

Elementary Principles of Reinforced Concrete Construction.—By Ewart S. Andrews, B.Sc., Lecturer in Theory and Design of Structures at Goldsmith's College, New Cross, London. Publishers, Scott, Greenwood & Son. Cloth; 4½ x 7 inches; pages xi. + 195; 57 text figures. Price, $1.00 net.

Of the various elementary texts in reinforced concrete this is one of the best. The author has the faculty of being able to state the essentials of his subject in a clear and convincing manner to those whose knowledge of mathematics is limited. This is partly due to simplicity and directness of statement and partly to the excellent word-illustrations of the joint action of concrete and steel in a reinforced member. Numerous numerical examples are also given which will undoubtedly reassure the beginner in his application of the formulas to actual problems.

The introductory part of the book comprises a brief historical review of the use of reinforced concrete, and a lengthy statement of the notation employed—that of the Concrete Institute—after which the author proceeds with a discussion of the properties of concrete and steel, loads, working stresses, bending moments, and the distribution of loads on slabs. The latter is covered particularly well for a short text book. After this, direct compression and bending on reinforced concrete members receive full attention, adequate consideration being given to double reinforcement, an important feature of arch ribs, walls and chimneys. Chapter IX. contains an interesting and somewhat novel graphical treatment of reinforced concrete beams, based on the methods of Professor Mohr. While only of academic interest in the case of simple sections, it will be found of use in handling irregular or unusual ones. The closing chapters concern shearing stresses, deflections, columns, leading systems of construction and twenty typical exrcises. A few common mathematical tables are also included.

Apart from the disadvantage of a notation differing considerably from that now regarded as practically standard on this side of the ocean and the characteristic British terminology, the book is thoroughly acceptable. Some slight errors exist, as in the use of the word "strain" for "stress" on page 22, the numbering of two figures the same (22), and a few misspelt words. On the whole, the author's work ought to prove very useful and helpful to the young designer in reinforced concrete.

Steel Rails.—By William H. Sellen. Published by D. Van Nostrand Company and Constable & Company. 523 pages; 7¼ x 10¼; 361 illustrations and 33 folding plates. Price, $12.50 net.

Reviewed by T. R. Loudon.

Since the introduction of the use of the steel rail, no other steel commodity has received so much attention, both by the railway companies and the steel manufacturers. It is not so long ago that the worst possible confusion existed as to the proper section of rail for a given traffic condition. Of late years, however, more or less uniformity has been reached, but this state was not brought about without a tremendous amount of discussion. At the present time, so heavy are the traffic conditions that the question of proper rail specifications is again giving rise to another important series of discussions. All this discussion, past and present, is so widely distributed throughout the technical literature that it is an almost insurmountable task to begin to follow any given phase from the beginning up to the present time. To those familiar with the manufacture of the steel rail, this is only too well known. To pick and choose and intelligently synopsize the above referred to discussions is a work that is worthy of note. This is a task that has been undertakeo and carried out in an extremely creditable manner by the author of this book. From the historical standpoint alone the information compiled in this book is invaluable.

The first chapter is written with the evident purpose of tracing the evolution of the present-day rail section. The purely historical data is interesting. Apart from this, the matter is so put together that the reader sees very clearly the reasoning that has led to the use of the modern rail section. In summing up this chapter, the author points out very properly that the ability of a rail to resist the loads to which it is subjected is dependent as much upon the character of the metal as upon the section. The point is very properly made, coming, as it does, in the first chapter. These last two paragraphs could stand being more prominently set up.

Chapter II. deals with the pressure of the wheel on the rail. In this section of the book the author goes into the additions that must be made to the static wheel loads in order to arrive at the actual load under running conditions. The effects of the various factors, such as the lack of balance in the reciprocating parts of the locomotive, of irregularities in the track, rocking of engine, flat spots on wheels, are considered in detail. The data given is exceedingly extensive and well presented. While it is always possible to arrive at a definite figure for the unbalanced forces due to reciprocating parts of a locomotive, it is not very easy to arrive at a definite method of analysis of the other known causes of excess pressure on a rail. The author quotes the various theories and tests in a very interesting manner. The information given on electric cars and upon ordinary cars is extremely up to date.

Chapter III. is devoted to supports of the rail. The first part of this chapter is taken up with the description of the various forms of ties used. The descriptions are brief, and the reasons for and against the use of the various forms of ties are to the point. A large portion of this section is devoted to the discussion of the ordinary wooden tie. Some interesting data is given on forestry as applicable to the production of railroad ties. A comparison of the half-round ties, which are used a great deal in Europe, with the American form of tie is made, and it is quite clearly shown that not only from the standpoint of desirability for track support, but also from the standpoint of economical production, the half-round should be used. Descriptions of various forms of tie-plate and fastenings are then given. The last part of

the chapter is devoted to a discussion of the strength of ties under various treatments.

"Stresses in the Rail" is the heading for Chapter IV. The first portion of this chapter is more given over to discussing wear on tires, which is well put together and interesting, but is not very well worked into the subject of the chapter. A statement is made farther on relative to the heating of a rail due to slipping of drivers. It is stated that the running surface is hardened by this overheating and cooling, due to the surrounding metal conducting the heat away quickly. Quite true, the surface of a rail is heated by slipping of drivers. As the author points out, the shower of sparks when slipping takes place attests to this, but even though a small portion of the rail were heated, there is no doubt that the surrounding metal cannot conduct the heat away quickly enough to produce hardening. Certainly the effect cannot be as the author states: "Similar to quenching steel from high temperature in water, etc." In cold or moist weather some effect might be noticed, but this would be doubtful. In the discussion of bending and shearing stresses and the efficiency of rail joints a great deal of very accurate information is quoted. For use as splice-bars, the author favors oil-treated steel, presumably about fifty points of carbon. The statement is made that "oil-treated steel is as much in advance of high-carbon steel as is the latter over soft steel." Presumably this refers to the higher carbon steels being oil-treated. The point is not clear. The context, however, quotes a fifty-point carbon steel used by Cambria Steel Company. The information quoted on Rail Splices is well worth careful consideration.

In Chapter V. the strength of the rail is taken up. A great deal of information on repeated stresses is given and applied to the case of a rail under service. It might have been as well to have gone more carefully into the discussion of the internal structure of steel than is done at the beginning of the chapter. The subject is one requiring careful consideration or it had better be left alone. The discussion of what constitutes a crystal and what is referred to by a crystalline grain in steel is one which is very confusing unless the reader is familiar with the study of alloys, and the iron carbon series in particular. The chapter also deals with the effect of temperature on the strength of a finished rail and on the methods of testing.

The Influence of the Detail of Manufacture is discussed in Chapter VI. The first portion of the chapter is taken up with a description of the methods of manufacture of steel and the influence of certain elements on steel. There are certain inaccuracies in the descriptions that are inevitable in a synopsis. For instance, in the description of the Bessemer process it is stated that, "The combustion of this carbon (in the molten pig iron) increases the heat of the metal, and the flame . . . is at first red, but rapidly becomes brighter, etc." No mention is made of the burning of the silicon, which, in our present Acid Process, is the most important element in maintaining the temperature of the process. The first "flame" while the silicon is burning as a matter of fact is not a true flame. This is doubtless what the author had in mind, but the description is loose. In discussing the treatment of the ingot the author has gone to considerable pains in collecting the most up-to-date information. The section on mechanical work is also very well put together.

The last chapter is made up of various rail specifications, and on account of the wide range given is valuable.

As stated before, there are a number of plates. The drawings show up well on the dead white paper, the dimensions being very clear.

The book is a credit to the author, and is evidently the result of an enormous amount of labor in gathering information.

PUBLICATIONS RECEIVED.

Canadian Railway Club.—Official proceedings of the club, Montreal. James Powell, secretary.

Cloth Pinions.—Illustrated bulletins. Issued by the Canadian General Electric Company, Limited, Toronto, Ont.

Air Compressors.—Illustrated bulletin. Issued by the Canadian General Electric Company, Limited, Toronto, Ont.

Map of Cowganda Mining Division.—Issued by the Geological Survey of Canada, and covering twenty-eight townships in that district.

Forest Products of Canada.—Statistics as compiled by R. G. Lewis, B.Sc.F., on pulpwood. Issued by the Department of the Interior, Canada.

Electricity in Excavation and Construction Work.—Illustrated bulletin, 28 pages. Issued by the Canadian General Electric Company, Limited, Toronto, Ont.

Ontario Agricultural College.—Thirty-eighth annual report. Issued by the Ontario Department of Agriculture, Toronto.

Inspectors of Factories.—Twenty-fifth annual report of inspectors. Issued by the Provincial Government, Toronto, Ont.

Report of City Engineer, Hamilton.—Annual report for year ending December 31st, 1912, of Mr. A. F. Macallum, city engineer.

Queen Victoria Niagara Falls Park.—Twenty-seventh annual report of the Commissioners. Issued by the Provincial Government, Toronto, Ont.

Prisons and Reformatories.—Forty-fifth annual report of the Inspector of Prisons and Public Charities. Issued by the Provincial Government, Toronto, Ont.

Rain Statistics, Compiled by the Department of Trade and Commerce for the Year ended March 31st, 1912.—Part V. of the annual report of the Department.

The Analysis of Black Powder and Dynamite.—Technical bulletin by Walter O. Snelling and C. G. Storm. Issued by the United States Bureau of Mines, Department of Interior.

The Currents in the Entrance to the St. Lawrence, from investigations of the tidal and current survey in the seasons of 1895, 1911, and 1912. Published by the Department of the Naval Service at Ottawa.

Revenues and Expenses of Steam Roads in the United States for the Month of April, 1913.—Bulletin No. 53, prepared by the Division of Statistics, and issued by the Interstate Commerce Commission.

The Determination of Internal Temperature Range in Concrete Arches.—By C. S. Nichols, B.C.E., and C. B. McCullough, B.S. Bulletin No. 30 of Iowa State College, Engineering Experiment Station.

Trade and Navigation Statements.—Unrevised monthly statements of imports entered for consumption and exports of the Dominion of Canada for the month of April, 1913. Issued by the Minister of Customs, Ottawa.

The Inspector of Prisons and Public Charities' Report.—Forty-fifth annual report on hospital for feeble-minded and epileptics for the year ending October 31st, 1912. Issued by the Provincial Government, Toronto, Ont.

The Theory of Loads on Pipes in Ditches, including Tests of Cement and Clay Drain Tile and Sewer Pipe.—By A. Marston and A. O. Anderson. Bulletin No. 31, Engineering Experiment Station of Iowa State College.

Topographical Surveys Branch Report.—Contains the annual report of the topographical survey branch for the year 1911-1912. 260 pages. Illustrated, and includes 17 sketch and topographical maps. Issued by the Department of the Interior, Ottawa.

Report of the Railway, Telegraph and Telephone Department of the Province of Saskatchewan for the year ending February 29th, 1912.—A pamphlet containing over

sixty pages of reports from officials in charge of the several branches of the department.

The South African Institute of Electrical Engineers.—Contains transactions of the Institute and copies of papers read by members, among them an interesting paper on "Water-power Plants," by W. Eldson-Dew. Issued by the Institute. The Corner House, P.O. Box 4563, Johannesburg.

Technical Paper No. 44, United States Bureau of Mines.—A paper by H. H. Clark on Safety Electric Switches for Mines, based on study and investigation of causes of mine accidents, and dealing with the design of switches to prevent gas ignition upon operation under load.

Transactions of the Institute of Marine Engineers.—Contains copy of papers on "Thermodynamics and Refrigeration." By G. James Wells, and lecture on "Refrigeration," by Robert Balfour. Issued by the Institute, 58 Romford Road, Stratford, Eng.

Engineering Experiment Station.—Bulletin No. 31.—Illustrated. Contains papers on "The Theory of Loads on Pipes in Ditches," and "Tests of Cement and Clay Drain Tile and Sewer Pipe," by A. Marston and A. O. Andrews. Issued by the Iowa State College of Agriculture and Mechanic Arts, Anus, Iowa.

Engineering Experiment Station.—Bulletin No. 30.—Illustrated with maps inset. Contain papers on "The Determination of Internal Temperature Range in Concrete Arch Bridges," by C. S. Nichols and C. B. McCullough. Issued by the Iowa State College of Agriculture and Mechanic Arts, Anus, Iowa.

Engineering Experiment Station.—Bulletin No. 31.—Illustrated. Contains papers on "The Theory of Loads on Pipes in Ditches" and "Tests of Cement and Clay Drain Tile and Sewer Pipe." By A. Marston and A. O. Anderson. Issued by the Iowa State College of Agriculture and Mechanic Arts, Anus, Iowa.

Progress of Stream Measurements.—Report by F. H. Peters, C.E., for the Department of the Interior. A 310-page book, with 62 plates and numerous maps and tables covering the work accomplished by the Department in the measurement of stream flow during the year 1911, by P. M. Sauder, C.E., chief hydrographer.

Ohio State Board of Health.—Monthly bulletin containing articles relating to public health, the significance of occupational diseases, and a brief outline of the two new divisions of the State Board of Health recently created by legislative action. Prepared by E. F. Campbell, Ph.D., M.D., and issued by the Board, Columbus, Ohio.

United States Bureau of Mines.—Report No. 37.—Containing a paper by Irving C. Allen on "Heavy Oil as Fuel for Internal Combustion Engines." A 36-page pamphlet presenting the result of an extended research for some means of more effectivly burning heavy asphaltum oils as fuel for steam-raising and for engines of internal combustion type.

Report of the Minister of Public Works.—Report on the Ottawa River storage and notes on a visit to the Panama Canal; also on geodetic levelling between Stephens, Minn., and Winnipeg Beach, Man., and between Trenton, Lake Ontario, Orillia and Lake Couchiching, Ont. Fully illustrated. Issued by the Department of Public Works, Ottawa.

United States Bureau of Mines.—Bulletin 62.—Dealing with the Mine Rescue and First Aid Conference, held last September in Pittsburg, Pa., containing addresses and discussions and reports of sub-committees. The bulletin also contains resolutions adopted at the Conference and the proposed constitution for a permanent national mine rescue and first aid association.

Progress of Stream Measurements.—Report of F. H. Peters, C.E., on stream measurements for the calendar year of 1911. The report gives a brief outline of the methods of obtaining and compiling data, and gives in a tabulated form almost all of the records of stream flow during 1911.? Illustrated, and contains map showing the gauging stations in Alberta and Saskatchewan. Issued by the Department of the Interior, Ottawa.

Super-heated Steam Engines. Economical and reliable generation of power by over-type super heated steam engines from a paper read by W. J. Marshall, A. M. I. Mech. E., before the British Association at Portsmouth. The descriptions and data relative to the construction and operation of the Garrett engine, manufactured by Messrs. Richard Garrett & Sons, Limited, Leiston, Suffolk, are most interesting, and cover twelve pages of 10 x 12 concisely printed type.

The Journal of the Royal Astronomical Society of Canada, May-June number, containing an interesting article by Prof. A. C. Chant on the extraordinary meteoric display observed on the evening of February 9th, 1913. The article deals very scientifically with the occurrence, and contains reports of observations from many localities throughout Canada. Another article of interest is by W. F. King, chief astronomer, Ottawa, bearing upon the new reflecting telescope for the Dominion Observatory.

Some Facts about Treating Railway Ties.—Parts I. and II. of which were published in 1912, and were devoted to descriptions to various processes of wood preservation and improved methods of treating railway ties. Parts III., IV., V. and VI, dealing with the mechanical life of ties, a comparison of zinc chloride with creosote for preserving, a history of wood preservation in Europe and America, and a list of treating plants, together with their location, capacity, processes, etc., have just been published. The treatise is bound in three pamphlets, aggregating 200 pages, 6 by 9 inches, and costing $1.50 per set.

CATALOGUES RECEIVED.

Mikado Locomotives.—Illustrated bulletin issued by the American Locomotive Co., New York, U.S.A.

Architecture.—A catalogue of books relating to architecture. Issued by B. T. Batsford, 94 High Holborn, London.

Channon's Review.—Illustrated catalogue of the company's general machinery and supplies. Issued by the H. Channon Co., Chicago, Ill.

Armstrong Drop Forged Steel Wrenches.—A 32-page illustrated booklet covering wide range of wrenches with sizes and prices, of Armstrong Brothers Tool Co., Chicago.

Direct Current Apparatus.—Electrical catechism concerning the conventional questions asked by prospective buyers. Illustrated. Issued by the Fairbanks, Morse and Co., Chicago, Ill.

Alternate Current Apparatus.—Illustrated bulletin containing general information in regard to alternate current apparatus. Issued by the Fairbanks, Morse and Co., Chicago, Ill.

Clyde Iron Works Co.—An original style of catalogue concerning their output of hoisting machinery may be obtained on application to the Clyde Iron Works, Duluth, Minn., U.S.A.

Concrete Machinery.—170 page illustrated catalogue of the different types of concrete machinery manufactured by the company. Issued by the London Concrete Machinery Co., Ltd., London, Ont.

Electric Arc Welding Apparatus.—28-page catalogue, well illustrated and containing a complete description of the new multiple unit arc welding outfit. Issued by the C. and C. Electric and Manufacturing Co., Garwood, N.J.

Comparison Between Low Pressure Water Turbines and Centrifugal Pumps and the inferences applied to the construction of irrigation and drainage installations. Illustrated. Issued by the Escher Wyss and Co., Zurich.

The Labor Saver.—Illustrated catalogue devoted to the automatic handling of materals in construction, published in the interest of efficiency and economy in production. Issued by the Stephens-Adamson Manufacturing Co., Aurora, Ill.

What Users Say About the United States Graphite Company's Mexican boiler graphite. A handsomely-bound, printed and well-edited 64-page booklet dealing with scale in boilers and its prevention by the use of the company's product.

Modern Blue-Printing.—By P. M. Morgan, an 8-page pamphlet dealing with the Pease "Peerless" continuous blue-printing equipment, and abstracted from an article appearing in May 29th issue of *The Canadian Engineer*, published by E. R. Watts, Canada, Ltd., Canadian Agent for the C. F. Pease Co., of Chicago.

Steel Armoured Concrete Pipes for Pressure, Drainage and Water Conduits.—A 20-page catalogue descriptive of Siegwart pipes of reinforced concrete, together with tables of measurement, results of tests and diagramatic illustrations of stresses. The International Siegwart Beam Co., Lucerne, Switzerland, Canadian Agency, F. T. Kaelin, 611 Power Building, Montreal.

Cheap Steam and Machine-Firing.—A 28-page illustrated catalogue containing concise description of the construction and operation of the Gold Medal machine stoker, reports of active tests, and machines in situ on leading types of boilers, the drawings of which should be especially interesting to steam users. Copies may be obtained gratis from G. H. Tod, Manning Chambers, Toronto.

The Explosive Concrete Pile.—A set of bulletins issued by the International Siegwart Beam Company concerning concrete piles "exploded" at the base to afford efficient expansion desirable for foundations on bad ground. Records of trials are contained therein and the bulletins are well illustrated, and printed in English, French and German. Canadian agent, F. T. Kaelin, 611 Power Building, Montreal, Que.

L. S. Starrett and Co.—Illustrated catalogue, No. 20, 320 pages, contains interesting descriptions, illustrations and prices of all kinds of tools for machinists, carpenters, draftsmen, engineers, chauffeurs and other mechanics. In addition there are many pages of data and tables such as metric conversion tables, decimal equivalents, weight computing tables, tapers and angles, wire gauge tables, etc. The arrangement of the catalogue has been somewhat changed from that of No. 19, which makes it easier for reference. Issued by L. S. Starrett and Co., Athol, Mass.

The "Stoney" Sluice and its Application to Water Storage and Control.—144-page catalogue, fourth edition, descriptive of "Stoney" control sluices of which Ransome and Rapier, Ltd., London and Ipswich, England, are the manufacturers. Contains many interesting illustrations of installations and general information relative to water control, ice and flood conditions, general properties of weirs, etc. The work is supplemented by numerous tables and diagrams and the items are carefully indexed making the publication one of value for waterworks' engineers. Issued from the London office of Ransome and Rapier, Ltd., 32 Victoria Street, S.W., London, England.

COAST TO COAST.

Toronto, Ont.—The new custom house planned with other new Dominion Government buildings in this city, will cost $2,000,000 when completed. Yonge and Front Streets will be widened to provide an approach to the new buildings. The new Union passenger station will also cost in the neighbourhood of $2,000,000.

Winnipeg, Man.—Applications have been invited in London, for subscriptions for a city of Winnipeg loan of $3,450,000 at 4½ per cent., the price being 97. The loan, which is redeemable at par in 1963, will be utilized for the extension of the civic water supply and electrical and other public works. Winnipeg's existing liabilities, exclusive of the present issue, amounts to nearly $35,000,000.

Halifax, N.S.—The Halifax Automobile Association has inaugurated a good roads movement along unique lines. On the 23rd inst., all the auto-owners in the city will start out in their cars with over-all laborers in each, and a plan to thoroughly repair a bad stretch of some twenty miles of road outside the city. Finding that previous financial efforts have failed, the owners now intend to devote their own muscle to improving the highways.

Victoria, B.C.—Plans for the harbor work for this season at Victoria have now been completed by the engineering branch of the Public Works Department at Ottawa, and as soon as the specifications are printed tenders will be called for. The work calls for the building of two peirs, one of a thousand feet and the other eight hundred and seventy feet in length. They will be built of concrete and crib work, and will provide three berths for the largest liners. The estimated cost of the work is around two million dollars, and it is said that Victoria will be made a real national port, capable of handling the largest steamers and of taking care of the development which is looked for with the opening of the Panama Canal.

Ottawa, Ont.—Early developments are expected in connection with the Chats Falls water power which the Ontario Hydro-Electric Commission is endeavoring to secure Mayor Ellis and members of the commission are at Chats Falls looking over the location, and it is understood that immediate action will be taken to hurry matters along. The commission has already served formal notice of expropriation on the private owners of the water powers. But a more important movement is that which it is understood is contemplated by the Dominion Government, the making of complete investigations with a view to cancellation of the transfer by the Laurier government of the most important part of the water power. Ottawa is vitally interested in the matter, as if the Hydro-Electric Commission secures the water powers at Chats Falls, the current for the municipal electric department will come from the plant which would be erected there to serve eastern Ontario.

Victoria, B.C.—The proposal of Sir Richard McBride that the governments of Canada and the United States shall unite in constructing a trunk line of railway that will connect the Alaskan and Canadian lines, is being received with favor wherever it is mentioned. In a private letter from Hon. J. F. A. Strong, Governor of Alaska, he expresses his hearty sympathy with the proposal and his willingness to do whatever he can to promote the mutual welfare of Canada and Alaska. Speaking generally, the proposed railway would be a main artery carrying the life blood of progress to an area of more than three-quarters of a million square miles

of territory rich in natural resources of various kinds. Northern British Columbia and the Yukon Territory contain, by careful estimate, sufficient arable land to support a million people by agriculture. The Alaskan Agricultural Bureau, after careful investigation, has reported that "the total tillable and pasture land of Alaska is estimated at 64,000,000 acres," and adds, "all the crops that can be raised in Sweden, Finland and the northern provinces of Russia—potatoes, root crops, barley, oats, carrots, beets, turnips and celery—can be raised there." The bureau also says that "there is more agricultural land in the Lanaux Valley than is now under cultivation in the corresponding regions of Norway, Sweden, Finland and the four northern provinces of Russia." The mineral wealth of the whole region is enormous. This imperial area, which is almost equally divided between Canada and the United States, is at present absolutely cut off from land communication with existing railway systems, and can only be reached by a sea voyage of several days' duration, which militates very greatly against its development. There are already between five hundred and six hundred miles of railway, either constructed or in the course of construction, in this great and only meagrely exploited region.

Montreal, Que.—The financial stringency will have little effect, it is expected, on the city's programme of public works for the summer. No attempt has yet been made to raise the new $13,000,000 permanent loan, for which authority was secured some time ago. The city is not now in actual need of the money, and to place a new loan on the market at a time when it is not likely to meet with success, would, it is felt, only damage the city's credit unnecessarily. "We shall have no difficulty in raising any money we may need on temporary loans," J. Pelletier, City Comptroller and Auditor, said recently, "and then when the market improves we can float a permanent loan and pay off the temporary ones. We have not enough money actually in hand to meet the year's programme, because we naturally borrow money as we need it to save the interest. Besides, it is impossible to say beforehand how much of the work will be done. A few week's rain, for instance, might interfere with the programme very materially. But there is no danger of work being held up for lack of funds, so far as Montreal is concerned. We can always secure all we need on temporary loans." The city, however generously inclined, it was stated by a city official, has no authority to give financial assistance to outside municipalities, where work has had to cease for lack of money.

Montreal, Que.—The duties of a road engineer in Montreal are no sinecure—according to John R. Barlow, the city road surveyor. Montreal, according to Mr. Barlow, is built on a strange geological formation and is subjected to extraordinary climatic conditions which make the construction of roads very difficult. "Running right under the city," he said, "are great belts of blue clay and quicksand. During prolonged rains, these belts expand forcing the surrounding earth outwards. When the hot weather comes, they contract and there is a subsidence of the surrounding earth. If this occurs under a roadway, it does not take an expert to see what will happen. Every street in Montreal has to be built according to its own peculiar conditions. Permanent paving is to my mind the only solution of the street problem in Montreal. There should be a good foundation of concrete to prevent the roadway from sinking. Just to illustrate our difficulties. We sometimes find in repairing a permanent pavement, that the earth underneath the concrete bed has been completely washed away, leaving a concrete bridge from side to side of the street, and this has to support the full weight of the traffic. The macadamized road cannot last long in Montreal. You may build a road as well as you like, but if you have a keen winter the frost will sink into it as much as six feet and when that frost comes out in spring it will break up the road. There has been some criticism lately with regard to the stone we use on our macadamized roads. We are charged with wasting money on limestone. As a matter of fact we have never used limestone, except perhaps on a back street or two near a quarry. The greater part of the stone we use is scissel, which has a closer grain even than granite and has been pronounced by experts to be one of the best macadamizing stones on the continent.

Quebec, Que.—The necessity of completing the work of dredging the north channel of the St. Lawrence below Quebec as soon as possible is receiving the attention of the Marine Department. For this purpose in a very short time an additional dredge, one of the largest in the world, which will be capable of discharging into barges or its own hoppers will be put into commission. The work will thus be completed in a shorter time. Representations for the early completion of the work have been made by the Quebec board of trade on the ground that as new and larger vessels are being continually added to the St. Lawrence route the north channel should be finished. In order to obtain a 35-foot channel at extreme low tide with a width of 1,000 feet by way of the north channel below Quebec from St. Jean Island of Orleans to Goose Cape, 18,000,000 cubic yards of material will have to be removed. Of this amount 3,000,000 cubic yards have been dredged up to date. With the new plant it is expected that all the work will be concluded in four more years. The completion of the dredging of the north channel will greatly enhance the value of the St. Lawrence route for it is much superior to the south channel. With the proposed aids to navigation the north channel will be easier to navigate than the south. It will have a very short length of 35 feet and will not require buoys and lightships as the present long and tortuous channel. It will also be easy to navigate in the winter months.

Ottawa, Ont.—Fairly satisfactory is the way Mr. Joseph Race, city bacteriologist, sums up the results of the tests made of the city water during June. During the month 904 samples were examined, this number being made up as follows: Water city supply, 187; wells, general, 72; well, Ottawa Dairy Co., 19; water from carts, 14; water, miscellaneous, 15; milk, 462; cream, 6; hypochlarits, 120; sputum, 5; diptheric swabs, 4; total, 904. The bacterial contents of the ward samples of water has been above the average during the past month but it is now again normal. No adequate reason can be found for this. The city samples, on the whole, have been fairly satisfactory. The only change made during the month as to hypochlorite was to increase the amount added at Queen Street from 100 to 150 lbs. per day. The private wells examined during the month have generally shown a marked increase in quality but a number of those previously reported as contaminated still contain organisms indicative of past pollution. In connection with the bacteriological examination of well water or any description of water, Mr. Race points out that the tests employed in the direction of the detection of organisms of farcal or escremental origin and that the presence of such organisms does not necessarily imply that the sample containing them is injurious to health. If the organisms are derived from a healthy person or animal no ill effects would be observed, but if the sewage is that of a person suffering from typhoid

or dysentery the water would be infected and would produce disease in a susceptible individual. It is this difference between an infected water and a contaminated or polluted water that must be borne in mind. A polluted supply is dangerous because it may become infected at any time by a person suffering from typhoid or by a carrier.

PERSONAL.

Mr. BION J. ARNOLD, of Chicago, assisted by Mr. G. W. MOYES, of this city, has commenced the investigation of street railway traffic conditions in Toronto.

E. F. BRADLEY has been appointed manager of the Toronto office of the International Engineering Works, Limited.

K. S. MACLACHLAN, B.A.Sc., has recently been appointed superintendent of the Metals Chemical Company, of Welland, Ont., ore smelters and refiners.

Mr. WILLIS CHIPMAN, of the firm of Chipman & Power, Toronto, has been called into consultation by the city of Edmonton, Alta., in regard to the site of the proposed filtration plant.

Mr. J. G. S. HUDSON, consulting mining engineer, Department of Mines, Ottawa, is at present in Nanaimo, B.C., on an investigation trip concerning explosives. It is understood that one of the measures to come before the Federal House next session is a new Explosives Act.

ARTHUR H. BLANCHARD, M. Can. Soc. C.E., Professor of Highway Engineering in Columbia University, has been retained as Consulting Highway Engineer by the Department of Efficiency and Economy of the State of New York.

PREVOST HUBBARD, in charge of the Division of Roads and Pavements of the Institute of Industrial Research, Washington, and lecturer in Engineering Chemistry in Columbia University, has been retained as Consulting Highway Chemist by the Departmnt of Efficiency and Economy of the State of New York.

Mr. W. ARMSTRONG, Canadian manager of the Canadian P. J. Mitchell Company, Limited, has resigned his position in order to become managing-director of the newly-formed Armstrong-Kerr Company, of Vancouver, contracting engineers. Mr. Armsstrong is now en route to Vancouver, having returned last week from England, where he secured several desirable agencies for his new firm.

Mr. D. EWART I.S.O., chief architect, Department of Public Works, Ottawa, is on a tour of official inspection across the Dominion. Mr. Ewart will stop at all places where important public works are in progress. The Department at present has several large undertakings under way in the west, and more of them planned, such as large dry-docks on the Pacific coast and storage elevators at various western points.

Mr. RICHARD V. LOOK, of Louisville, Ky., formerly vice-president of the American Creosoting Company, has been elected president of the Canada Creosoting Company, Limited, and will move to Toronto this week to assume his duties. Mr. Look's office will be in the company's head office in the Canadian Pacific Railway building, Toronto. As president of the company he succeeds Mr. Hurt, the president of the American Creosoting Company, who acted temporarily as president of the Canada Creosoting Company, Limited, during its organization.

Mr. A. E. GRANT has been appointed managing-director of the Canadian British Insulated Company, Limited. For the last twelve or thirteen years Mr. Grant has been with the British Insulated and Helsby Cables, Limited, England, which company is the chief stockholder in the Canadian firm. Since 1906 he has been manager and chief engineer of the Cardiff office, which controls the firm's business in the south-western counties of England and in South Wales. He is a brother of Mr. Lawford Grant, president of the British Insulated Company, Limited, who recently resigned his former position as managing-director in order to accept an important post with the Eugene Phillips Electrical Works, Limited.

COMING MEETINGS.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Annual Meeting in Regina, September 16th, 17th and 18th. General Secretary, Major Drum, Ottawa; Local Secretary, Dr. Murray, Regina.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D.C.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Meeting to be held at Lethbridge, Alberta, on August 5th and 6th, 1913. Secretary, Norman S. Rankin, Calgary, Alta.

AMERICAN CONCRETE INSTITUTE.—First Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

READERS SHOULD NOTE THE REMOVAL OF THE LIST OF CANADIAN TECHNICAL AND MUNICIPAL SOCIETIES FROM THIS PAGE TO PAGE 94, IN THE REFERENCE SECTION OF **THE CANADIAN ENGINEER.** BY THIS CHANGE, ALMOST AN ENTIRE PAGE OF READING MATTER IS ADDED WEEKLY

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for smal fee.

19752—June 30—Approving revised plan (G.T.R.), marked "C," of subway on Peter street, town of Port Hope, Ont.; and rescinding Order No. 19105, dated April 22nd, 1913, in so far as it approves of subway on Peter street, as shown on plan marked "B."

General Order No. 107—July 4—Prescribing Rules and Regulations governing fire guarding by railways under the Board's jurisdiction; and rescinding Order No. 16570, dated May 22nd, 1912.

19753—July 5—Authorizing C.P.R. to construct extension to existing spur for R. Home Smith, Toronto, in Lot 10, Con. C., Co. York, Tp. Etobicoke, Ont.

19754—July 4—Amending Order No. 2119, dated Nov. 28th, 1906, by striking out words "Grand Trunk" in fifth paragraph of operative part of Order and substituting therefor words "Applicant Company."

19755—July 4—Directing that Salisbury & Albert Ry. put guard rails on all bridges 50 feet or over in length, on its railway; work to be completed by August 20th, 1913.

19756—July 2—Directing that, within 90 days from date of this Order, C.N.O.R. install improved type of illuminated electric bell at crossing of Sidney street, Trenton, Ont., and thereafter maintain bell at its own expense.

19757—July 7—Authorizing C.P.R. to open for traffic portion of Kootenay Central Ry. between mileages 0.00 and 41.00, Golden to Spillimacheen, B.C.

19758—July 7—Authorizing C.P.R. to construct bridge No. 10.7 near Asphodel Station, Ont., and bridge No. 30.8 near Kendry Station, Ont.

19759—July 4—Granting leave to Hamilton Street Railway to cross, at rail level, T., H. & B. Ry., serving Steel Co. of Canada, Ltd., on Base Line between Broken Front and First Concession, Tp. Barton, now in city of Hamilton, Ont., subject to and upon certain conditions.

19760—July 5—Extending, until July 31st, 1913, time within which G.T.R. install gates required to be installed at crossing of Lake Shore Road, Vaudreuil, Que.

19761—July 5—Authorizing C.P.R. to construct branch lines for P. Burns & Co., Ltd., Calgary, Alta.

19762—July 8—Extending, until July 20th, 1913, time within which C.P.R. install gates at Bartlett avenue, Toronto, Ont., required to be installed under Order No. 18698, dated Feb., 1913.

19763—July 4—Approving revised location G.T.R. connecting track, from its line to the T., H. & B. Ry. line serving Steel Co. of Canada, Ltd., Hamilton, Ont.

19764—July 4—Authorizing T., H. & B. Ry. to construct two spurs in the city of Hamilton, crossing Hamilton Radial Electric Ry. and highway known as Burlington street (formerly Gilkinson street), to and into lands of the Steel Co. of Canada, Ltd., subject to and upon certain conditions. Spurs to be completed within three months from date of this Order.

19765—July 7—Extending, until Sept. 30th, 1913, time within which C.P.R. install gates at Osler Ave., North Toronto, Ont., required under Order No. 19229, dated May 10th, 1913.

19766—July 7—Extending, until Dec. 31st, 1913, time within which C.P.R. complete spur for Dominion Bridge Co., Ltd., at Islington, Ont., authorized to be constructed under Order No. 18998, dated April 5th, 1913.

19767—July 4—Authorizing C.P.R. to cross, at grade, with a side track on its Saskatoon Sub. Div., Saskatchewan Division, certain lanes and streets in city of Saskatoon, Sask., subject to and upon certain conditions.

19768—July 5—Authorizing V.V. & E. Ry. & Nav. Co. to construct three (3) industry tracks from a point on its main line, in Block 82, Dist. Lot 264 A, Vancouver, B.C., westwardly to and connecting with company's existing lines, opposite Block 3, Dist. Lot 200 A, said city; tracks to be completed within three months from date of this Order.

19769—July 3—Directing Quebec Oriental Ry. ballast its line, from Metapedia to New Carlisle, with complete lift of six inches of ballast; fencing, gates, wooden culverts, and all decayed portions of trestles be renewed on said line; work be completed by December 31st, 1913.

19770—July 5—Authorizing G.T.R. to construct siding for British Canadian Canners, Ltd., on Lot 20, Con. 2, Tp. Grantham, Ont.

19771—July 7—Approving C.N.R. plans showing Standard Stations Nos. 8, 5 and 4, for use on Eastern Lines, and its Standard Fourth and Fifth Class Station Buildings.

19772—July 8—Authorizing V.V. & E. Ry. & Nav. Co. to construct across Phillips Ave., municipality of Burnaby, B.C.

19773—July 5—Authorizing C.P.R. to construct spur from a point on northerly limit of right of way of existing spur to a point on Canadian Ingersoll Rand Co.'s No. 4 Siding, in Lot No. Cadastral 1539, city of Sherbrooke, Que.

19774—July 5—Authorizing C.P.R. to construct extension to existing spur for A. Snyder & Co., Ltd., Portage la Prairie, Man., in Lot 69, city of Portage la Prairie.

19775—July 5—Authorizing C.P.R. to construct spur for Benjamin S. Spaulding, Medicine Hat, Alta.

19776—July 8—Relieving C.P.R. of speed limitations on its line between mileage 75.85 and mileage 102.00 and between mileage 102.60 and mileage 112.00 (Weyburn-Lethbridge Branch).

19777—July 8—Authorizing C.P.R. to make two connections with the Otis Staples Logging Ry., at mileage 15.15, near Kimberly, B.C., in Lot 6078, Group 1, East Kootenay Dist., on Co.'s Alberta Division, Kimberly Subdivision.

19778—July 10—Authorizing C.P.R. to construct, by means of a grade crossing, a siding track across roadway between Lots 3 and 4, Con. 1, Tp. Sandford, Dist. Rainy River, Ont., at Minnitaki.

19779—July 10—Authorizing C.P.R. to construct additional track across fourteen (14) highways, mileages 35.8 to 47.9 (zero of said mileage being at Brandon), on main line, Manitoba Division, Broadview Subdivision. After diversion at mileage 46.46 is made and grade crossing constructed in accordance with Regulations of Board, company may close portion of present road allowance to be diverted within limits of its right-of-way.

19780—July 10—Refusing application of L. J. Chevrier to reopen the matter of C.P.R. taking certain lands in village of Rigaud, Co. Vaudreuil, Que.; and Order No. 18721, dated Feb. 13th, 1913.

19781—July 10—Amending Order 19603, dated June 17th, 1913, authorizing C.N.R. to construct spur along lane through Blocks 21 and 31, and to cross Isabella St.; and to construct spur along lane through Block 30, city of Saskatoon, Sask., by adding certain clauses.

19782—July 8—Authorizing C.N.R. to construct additional track across Main St., town of Humbolt, Sask.

19783—July 5—Extending, until July 31st, 1913, time for installing interlocking plant at crossing by C.N.R. of tracks of C.P.R. and G.T.R. Cos., near Ottawa, Ont., provided for under Order No. 11386, dated August 6th, 1910.

19784—July 9—Directing C.N.O.R. to construct suitable cattle passes, with five and one-half-foot clearances, where it intersects Robert T. McLaughlin's farm on Lots 24 and 25, Con. B., Tp. Westmeath, at points to be agreed upon between the parties.

19785—July 7—Authorizing C.N.O.R. to construct bridge across Little Sturgeon River, Tp. Beaucage, Ont., mileage 243.5 from Ottawa.

19786—July 10—Approving proposed Supplement No. 1 to Canadian Classification No. 11, as finally revised and submitted for approval by G. C. Ransom, Chairman of C.F.A., by his letter dated at Montreal, July 8th, 1913, to become effective on 20th day of August, 1913.

19787—July 10—Approving location Essex Terminal Ry. from a point on its line already constructed, on Lot 59, Con. 1, Tp. Sandwich West, to a point on or near Turkey Creek, Tp. Sandwich West, Ontario.

19788—July 10—Authorizing G.T.R. to construct siding from a point on its railway on Lot G, Rideau Front Concession, Tp. Nepean, Co. Carleton, Ont., now in city of Ottawa, into premises of Silicate Brick Co., under lease from Dominion Government. To be completed within three months from date of this Order.

19789—July 11—Authorizing G.T.R. to construct siding for Dominion Canners, Limited, on Lot 153, Con. 1, Tp. East Sandwich, Co. Essex, Ont.

19790—July 11—Directing G.T.R., forthwith, to employ watchman, to be on duty at crossing, on road leading from Beaconsfield to Ste. Genevieve, Que., from 8 a.m. to 7 p.m., until October 15th, 1913, and thereafter from May 15th, to October 15th, in each and every year until further order of Board; two-thirds of cost of said watchman to be paid by Ry. Co., and one-third by Municipality.

19791—July 10—Directing C.P.R. to employ watchman to be on duty at crossing of road leading from Beaconsfield to Ste. Genevieve, Que., from 8 a.m. to 7 p.m., until October 15th, 1913, and thereafter from May 15th to October 15th, in each and every year, until further Order of Board; two-thirds of cost to be paid by Ry. Co., and one-third by Municipality.

19792—July 11—Authorizing C.L.O. & W. Ry. (C.P.R.) to construct its railway at mileage 153.76 from Gleo Tay, across road allowance between Lots 28 and 29, Con. 1, Tp. Darlington, Co. Durham Ont.

19793—Approving revised location portion C.P.R. main line, Thompson Subdivision, from Station 341.87.6, in S.E. ¼ Sec. 18-20-18, W. 6 M., at mileage 6.76, to Station 392.45.8, in S.E. ¼ Sec. 13-20-19, W. 6 M., at mileage 7.72; and from Station 432.17.1, in N.W. ¼ Sec. 13-20-19, W. 6 M., at mileage 8.46, to Station 448.02.5, in N.W. ¼ Sec 13-20-19, W. 6 M., at mileage 8.67, zero of said mileages being at Kamloops, B.C.; and authorizing said company to construct additional track (double track), by means of grade crossings, across following highways; 3rd Ave., and 2nd Ave., Kamloops; road allowance in Sec. 12-20-18, W. 6 M.; road allowance in Lot 435, P.G.S.; and road allowance in Lot 346, P.G.S., both in Range 18.

19794—July 10—Authorizing C.L.O. and W. Ry. (C.P.R.) to construct across four (4) highways, Tp. Sidney, Co. Hastings, Ont., namely; mileages, (from Glen Tay), 79, Lot 33, Con. 1, Cemetery Road; 70.04, Lot 33, Con. 1, Kingston Road; 70.19, Lot 32, Con. 1, Forced Road and 79.61, highway between Lots 30 and 31, Con. 1, road allowance.

19795—July 11—Authorizing C.P.R. to construct proposed bridge across Red River, on its Kildonan Cut-off near Winnipeg, Man.; and rescinding Order No. 18618, dated February 3rd, 1913.

19796—July 16—Amending Order No. 19644, dated June 19, 1913, by striking out figures "11738.77" where they occur in recital and operative parts of said Order, after words "File No.," and substituting therefor figures "11738.73."

19797—July 15—Authorizing C.P.R. to construct road diversion in Sec. 7-12-23, W. 3 M, Sask., and construct main line, Alta. Division, across said diversion, by means of a grade crossing. After such diversion is made and grade crossing constructed company may close portion of present road allowance between Secs. 7 and 8-12-23, W. 3 M., within the limits of its right-of-way.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

RAILWAYS—STEAM AND ELECTRIC.

+—Ottawa, Ont.—The contract for the construction of twelve miles of the Morrisburg and Ottawa railroad, from Ottawa to Greely was awarded to R. J. TIERNEY AND COMPANY, Ottawa, at a special meeting of the shareholders. The cost of construction will average between ten and twelve thousand dollars a mile.

Vancouver, B.C.—Following a conference held between J. J. Warren, president of the Kettle Valley Line, and L. C. Gilman, of Seattle, vice-president of the Great Northern Railway, the announcement was made that tenders for the construction of the unfinished link across the Hope mountains from Coquehalla summit to Hope, on the Fraser River, a distance of about sixty miles, will be called for shortly. An early start on construction is assured as the time limit for receiving tenders will be short, and various prominent contracting firms have already inspected the route with a view to submitting tenders for the work.

BRIDGES, ROADS AND PAVEMENTS.

Arden, Man.—Tenders will be received up till the 6th of August, 1913, for the construction of steel truss bridge over White Mud River. Plans and specifications may be obtained from the Department of Public Works, Winnipeg and M. E. Broughton, secretary-treasurer.

+—Barrie, Ont.—The Town Council has awarded Messrs. CURRAN & CLEMENT the contract for the construction of pavement. The contract price is $1.23 per square yard for pavement and 25c. per lineal foot for curb.

Dundas, Ont.—Tenders will be received up till the 4th of August, 1913, for concrete work on a bridge. Plans and specifications may be obtained from John S. Fry, Town Clerk.

Halifax, N.S.—Tenders will be received up till the 2nd of August, 1913, for the construction of several bridges and culverts in the County of Hants. Plans and specifications may be obtained from the Department of Public Works and Mines, Halifax. E. H. Armstrong, Commissioner.

Halifax, N.S.—Tenders will be received up till the 8th of August, 1913, for the construction of several bridges and culverts in the County of Colchester. Plans and specifications may be obtained from the Department of Public Works and Mines, Halifax. E. H. Armstrong, Commissioner.

Huntingdon, Que.—Tenders will be received up till the 2nd of August, 1913, for the macadamizing of four miles of streets. Plans and specifications may be obtained from R. S. Feeny, secretary-treasurer.

+—Lindsay, Ont.—The Town Council has awarded Messrs. FOLEY & GLEESON the contract for paving William Street.

Montreal, Que.—Tenders will be received up till the 5th of August, 1913, for the construction of granite block pavement on Cote Street, Paul Road. Plans and specifications may be obtained from the Board of Commissioners. L. N. Senecal, Secretary.

Ottawa, Ont.—Provided the city's equipment is capable of carrying out the work most of the asphalt paving to be laid on lower town streets this year will be carried out by the city itself. City Engineer Currie has estimated for the work in each case a price lower than the tenders which have been submitted to the Board of Control. The following were the figures of the tenders received:—Clarence Street, Ottawa Construction Company, $7,430; Union Construction Company, $7,138; city engineer's tender, $7,030. Dalhousie, Cathcart to Sussex, Ottawa Construction Company, $18,400; Union Construction Company, $19,158; city engineer, $18,610. Spadina Avenue, Ottawa Construction Company, $5,500; Union Construction Company, $5,196; city engineer, $5,110. Dalhousie Street, St. Andrew to Cathcart, Ottawa Construction Company, $7,100; Union Construction Company, $7,533; city engineer, $7,270.

Regina, Sask.—Tenders will be received up till the 9th of August, 1913, for the construction of a grade across White Heron Lakes. Plans and specifications may be obtained from the Board of Control. A. J. McPherson, chairman.

Regina, Sask.—Tenders will be received up till the 9th of August, 1913, for the construction of a grade across Buffalo Coulee. Plans and specifications may be obtained from the Board of Control. A. J. McPherson, chairman.

+—Saskatoon, Sask.—The Canadian Pacific Railway has awarded Messrs. ALN & BLOOM the contract for a steel bridge with concrete abutments on Seventh Avenue. The contract price is $20,000.

Tarvia

Preserves Roads
Prevents Dust~

Atwater Avenue, Montreal, Quebec. Constructed with Tarvia Modern Pavement.

Tarvia vs. Plain Macadam

THE right-hand side of the above roadway was built with "Tarvia X." The left-hand side is plain macadam. The tarviated side is adequate to cope with the traffic. The plain macadam side is in persistent disrepair.

In previous years this roadway washed and gullied very badly in the spring and many tons of macadam were dislodged from different parts of this hill and deposited at the bottom by the spring rains.

Now, after a rain, the tarviated side drains quickly and easily to the gutter. The plain macadam side gets muddy and stays so for some time.

The tarviated side gets more than its share of the traffic because it affords superior traction, yet it is free of dust except for what is blown upon it from its dusty neighbor on the other side of the tracks.

As to maintenance, the tarviated side needs no attention, while the plain macadam is in frequent need of care. The cost of upkeep in the long run will be considerably greater for the plain macadam, and the results will be very inferior.

The initial cost of the plain macadam may have been a little lower, but the high maintenance more than wipes out the saving.

"Tarvia X" which was used on half of this road is a dense, viscid coal tar product which is immune from damage by water and frost. It forms a dense, plastic matrix about the stone, prevents internal movements of the roadway, and by reason of its plasticity, develops a surface that grows smoother with traffic.

Booklets Free on Request

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

+—Springfield, Ill.—The DOLARWAY PAVING COMPANY have been awarded the contract for the construction of 16,000 square yards of pavements.

St. Catharines, Ont.—As soon as a special committee appointed by St. Catharines makes a report favoring the contribution of that city towards the construction of a railway bridge over the Welland Canal, the Canadian Northern will seriously consider entering into an arrangement with the Canadian Pacific whereby both companies may jointly construct and use the bridge.

+—St. Thomas, Ont.—The Board of Works have awarded Mr. A. E. PONSFORD the contract for the concrete pavement on Southwick Street. The contract price is $1.25 per square yard.

▲—Toronto, Ont.—Tenders will be received up till the 6th of August, 1913, for the construction of a reinforced culvert. Plans and specifications may be obtained from Frank Barber, County Engineer.

▲—Toronto, Ont.—Tenders will be received up till the 6th of August, 1913, for the construction of a bridge. Plans and specifications may be obtained from Frank Barber, County Engineer.

Toronto, Ont.—Tenders will be received up till the 5th of August, 1913, for the construction of pavements. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Mayor.

Toronto, Ont.—According to the plans now prepared by Assistant City Engineer Powell, the city will expend $3,000,000 next year in bridges. The Bloor Street viaduct is the chief work planned and will consume a large amount of the sum named. The Gerrard Street bridge, the C.P.R. viaduct, Poplar Plains Road, Avenue Road and other bridges of less importance, make up the balance. The test holes for the Bloor Street viaduct and the Gerrard Street bridge have been sunk and the contracts for this work will be awarded late in the fall.

▲—Windsor, Ont.—The SARNIA BRIDGE COMPANY have been awarded the contract for three new bridges in the county. The contract prices being $7,300, $4,500 and $4,200 respectively.

LIGHT, HEAT AND POWER.

+—Lindsay, Ont.—The Hydro-Electric Power Commission has awarded BOVING & COMPANY of CANADA LIMITED, the contract for supplying large turbines and governors for the power plant at Wasdell's Falls. These units will be of similar size to those recently supplied by Boving and Company for Dams Nos. 2 and 5, in the Trent River, which have a combined capacity of 10,000 horsepower.

Toronto, Ont.—The Hot Point Electric Heating Company which has its central plant at Ontario, Cal., will locate a plant in this city. The estimated cost is $250,000.

GARBAGE, SEWAGE AND WATER.

▲—Bassano, Alta.—Tenders will be received up till the 15th of August 1913, for the construction of a sewage disposal works. Plans and specifications may be obtained from the John Galt Engineering Co., Ltd., consulting engineers and Geo, B. R. Bond, secretary-treasurer.

Edmonton, Alta.—By-laws authorizing an issue of $519,760 debentures for waterworks and an issue of $1,692,149 debentures for sewer extensions this year to be borne by the city at large, and an issue of $98,491.69 debentures to be expended on sewer extensions to be assessed to local improvements, have been passed by the city.

Montreal, Que.—Messrs. Hering and Fuller, of New York, the consulting engineers who drew up the plans for the filtration plant, have been asked to come here at once, This move, it is understood, is being made so that expert advice on the best manner of proceeding with the work on the plant may be obtained. It is likely that Mr. McLeod, the contractor in charge, will be asked to finish the work, though an extension of time will, of course, be necessary for the completion of the contract.

McLeod, Alta.—The $336,000 secured recently from the sale of town debentures will be spent as follows:—For the construction of a filtration plant and the improvement and extension of the waterworks system, $81,000; for the construction of a sewerage disposal plant in connection with the sewerage system, $50,000; for the extension of the sewerage, $36,000; for the construction and extension of the waterworks system and the extension and enlargement of the electric light system, $46,000; for the construction and extension of the municipal system of sewers, $23,000; and, for the erection and equipping of a building to be used for municipal purposes, $100,000.

Port Arthur, Ont.—Tenders will be received up till the 4th of August, 1913, for the excavating and refilling of trenches for sewers and water mains. Plans and specifications may be obtained from J. J. Hackney, commissioner of utilities.

St. Catharines, Ont.—The city's debenture issue of $45,000 for a new trunk sewer in the north-eastern end of the city has been sold in Toronto.

▲—Toronto, Ont.—Tenders will be received up till the 5th of August, 1913, for the construction of a number of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Chairman.

▲—Toronto, Ont.—Tenders will be received up till the 19th of August, 1913, for the construction of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Mayor.

Toronto, Ont.—Tenders will be received up till the 5th of August, 1913, for the laying of a 36-inch water main. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

Toronto, Ont.—The City Council have received a proposal from the Bell Filtration Company, Toronto, to install the new mechanical filtration plant. According to the offer of the company, they are prepared to install such a plant, which would be manufactured in Manchester, England. The plant would have a minimum capacity of 65,000,000 gallons and a maximum of 96,000,000. The equipment would include buildings erected by the company on foundations and excavations supplied by the city, consisting of basin, ground floor and one story, large enough for the addition of another 20,000,000 gallons, if necessary, to contain stores, laboratory, etc., with pipes three feet on each side for connection with the city pumps and mains. The plant would be tested to a pressure of 100 pounds to the square inch and they agree to put in a complete plant at a cost of $1,500,000.

▲—Welland, Ont.—Tenders will be received up till the 4th of August, for the construction of sewers. Plans and specifications may be obtained from *The Canadian Engineer*, 62 Church Street, Toronto, and James Hughes, Chairman Sewerage Committee.

+—Winnipeg, Man.—The DES MOINES BRIDGE AND IRON WORKS have been awarded the contract for the new 125,000 gallon reservoir to supply water to the Agricultural College. The contract price is $12,700.

INDUSTRIAL WORKS.

Cheverie, N.S.—Tenders will be received up till the 14th of August, 1913, for the construction of a wharf. Plans and specifications may be obtained from W. P. Morrison, Halifax, E. G. Millidge, Antigonish and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Dorchester, N.B.—Tenders will be received up till the 18th of August, 1913, for the reconstruction and enlargement of a wharf. Plans and specifications may be obtained from Geoffrey Stead, Chatham, N.B., J. K. Scammell, Fredericton and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Fort William, Ont.—The City Council has awarded Mr. M. H. BRADEN the contract for the erection of the new incinerator. The contract price is $12,990. The JOHN INGLIS COMPANY, Toronto, were awarded the contract for supplying the steel. The contract price is $3,550. Other firms tendered for the incinerator as follows:—Seaman and Penniman, $15,383; Moran Construction Company, $18,950; J. G. Pickard, $19,995.

Mannesmann Tube Co., Limited

51 VICTORIA SQUARE, MONTREAL

Hull, Que.—The A. H. Coplan Company will locate a foundry in this city. The estimated cost is $50,000.

Island River, N.B.—Tenders will be received up till the 5th of August, 1913, for dredging Island River, Gloucester Co., N.B. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Kenora, Ont.—Tenders will be received up till the 14th of August, 1913, for the construction of a wharf. Plans and specifications may be obtained from F. Y. Harcourt, Port Arthur, J. G. Sing, Toronto and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Kerrisdale, Point Grey, B.C.—It was announced at the municipal hall this morning that the time for receiving tenders for the incinerator has been extended till August 18th.

+—Kingston, Ont.—The City Council has awarded Messrs. McKELOEY & BIRCH the contract for installing the new steam heating system in the city's buildings. The contract price is $10,729. Messrs Symmons Bros., tendered $11,064 and Taylor and Hamilton, $12,198.

Little Current, Ont.—Tenders will be received up till the 12th of August, 1913, for dredging required here. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—New Westminster, B.C.—The Department of Public Works has awarded MESSRS. BROLEY & MARTIN, Vancouver, the contract for the construction of jetties at the Sandheads, at the mouth of the Fraser River.

Prince Albert, Sask.—The Imperial Steel and Iron Co. have located a plant in this city which will employ from 600 to 700 men. Modern machinery will be installed in the several departments. The company intends manufacturing horse shoes, plates for bridges, iron and corrugated sheeting.

+—Quebec, Que.—MESSRS. QUINLAN & ROBERTSON have been awarded the contract for the damming of the St. Charles River.

Rainy River, Ont.—Tenders will be received up till the 12th of August, 1913, for dredging required. Plans and specifications may be obtained from the Department of Public Works, Ottawa R. C. Desrochers, secretary.

+—Saskatoon, Sask.—The City Commissioners have awarded Messrs. McKENZIE & THAYER the contract for supplying 20,000 tons of coal. The contract price is $175,000.

St. John, N.B.—Tenders will be received up till the 5th of August, 1913, for dredging in St. John's Harbor. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

▲—Toronto, Ont.—Tenders will be received up till the 5th of August, 1913, for the equipment of the civic abattoir. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Mayor.

Toronto, Ont.—Tenders will be received up till the 19th of August, 1913, for the supplying of portable sewage pumping engines. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Chairman.

▲—Toronto, Ont.—Tenders will be received up till the 5th of August, 1913, for painting several bridges. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

▲—Toronto, Ont.—Tenders will be received up till the **25th of August, 1913, for the construction of a sea wall,** breakwater, ship channel and retaining walls. Plans and specifications may be obtained from the District Engineer and the Harbor Commissioners, Toronto; H. J. Lamb, Windsor; J. L. Michaud, Montreal; and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Vancouver, B.C.—H. E. Elgee, who is in charge of the breakwater scheme for the Sir John Jackson Company, will put in a tender for the government wharf, to be built in Burrard Inlet at a cost of $1,800,000.

+—Victoria, B.C.—The city has awarded the following contracts for supplies:—To MUSSENS, LIMITED, for dump cars; to the CANADIAN FAIRBANKS-MORSE COMPANY, for ventilating fans; to the HINTON ELECTRIC COMPANY for two 2 H.P. motors; to Mr. A. F. NYE, two hoisting outfits; to MUSSENS, LIMITED, for two drills; to HOLDEN COMPANY, LIMITED, one giant rock drill.

Walkerton, Ont.—Tenders will be received up till the 4th of August, 1913, for the construction of a concrete breakwater. Specifications may be obtained from A. E. McNab, Chairman of Committee.

MISCELLANEOUS.

+—Armstrong, B.C.—The Dominion Government has awarded Messrs. CAMPBELL & WILKIE the contract for the construction of a drill hall. The contract price is $11,800.

+—Belleville, Ont.—The Government has awarded Messrs. T. MANLEY & SONS the contract for the new dormitory for the Deaf and Dumb Institute. The contract price is $80,000. Mr. S. F. WHITAM has the contract for the other building.

▲—Cobalt, Ont.—Tenders will be received up till the 15th of August, 1913, for the erection of a three-story concrete and municipal building. Plans and specifications may be obtained from R. L. O'Gorman, town clerk.

+—Collingwood, Ont.—The Dominion Government has awarded MESSRS. HERRINGTON, BRYAN & HEALY the contract for the new federal building. MESSRS. BULL BROTHERS have been awarded the contract for the cement work.

+—Edmonton, Alta.—Mr. Geo Scath, Vancouver, has awarded the A. J. GILLIS COMPANY the contract for a business block. The contract price is $75,000.

+—Edmonton, Alta.—The A. McDonald Company have awarded Mr. A. J. GILLIS the contract for the erection of their warehouse. The contract price is $55,000.

Edmonton, Alta.—The Woodland Dairy Company will locate a plant in this city. The cost is estimated to be $50,000.

+—Fort Francis, Ont.—The Government has awarded MESSRS. SEAMEN & PENNIMAN the contract for the erection of a court-house. The contract price is $55,000.

+—Galt, Ont.—The Canadian Pacific Railway has awarded Mr. JAMES S. WEBSTER the contract for the construction of the company's freight sheds here.

+—Lethbridge, Alta.—The Lethbridge Industrials Ltd. have awarded MARINARO BROTHERS, Fernie, the contract for their factory building.

New Westminster, B.C.—Tenders will be received up till the 12th of August, 1913, for the erection of a public building. Plans and specifications may be obtained from Wm. Henderson, Victoria, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

North Vancouver, B.C.—Tenders will be received up till the 11th of August, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

+—Orono, Ont.—The Dominion Government has awarded Mr. THOM, of Collingwood, the contract for the erection of the new Armories. The contract price is $12,000.

+—Portage la Prairie, Man.—MESSRS. BEDMAN & OSBORNE have been awarded the contract for the erection of the parish hall. The contract price is $16,000.

Prince Albert, Sask.—Tenders will be received up till the 11th of August, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence. Eugene Fiset, Deputy Minister.

+—Regina, Sask.—Messrs. MELVILLE & DOWELL have been awarded the contract for the erection of a Jewish synagogue.

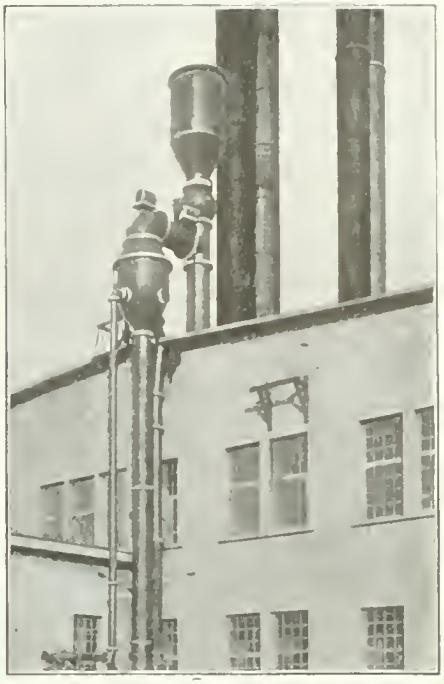
+—Simcoe, Ont.—The Dominion Government has awarded Mr. ROBERT E. GUNTON the contract for the erection of the Armories. The contract price is $30,000.

▲—Sudbury, Ont.—Tenders will be received up till the 6th of August, 1913, for the erection of a public building. Plans and specifications may be obtained from Thos. Hastings, Toronto, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

CONDENSING APPARATUS

specially designed to secure

GREATER STEAM ECONOMY



WORKS: WILLIAM and SEIGNEURS STREETS, MONTREAL

THE JOHN McDOUGALL CALEDONIAN IRON WORKS CO., Limited

Manufacturers of Boilers, Castings, Condensers, Elevators, Engines, Filters, Forgings, Hydraulic Machinery, Pumps, centrifugal and reciprocating, Steam Turbines, Tanks, Water Wheels, Water Works Plants.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction of the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

Sterilization Co.

Union Building, Clinton Street

NEWARK, N.J.

Also engineers for the electrolytic treatment of water.

A Perfect Weir Gage

Carries an unusually large card and will register without any reduction through a variation of two feet or on a two to one reduction through a variation of four feet.

Can be applied anywhere where fluctuation is within limit named and where great accuracy is desired.

In use on weirs, sewage disposal plants, irrigation and stream gaging.

Hydro Manufacturing Co.

700 BULLITT BUILDING, PHILADELPHIA, Pa.

Swift Current, Sask.—Tenders will be received up till the 5th of August, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

+—Temiskaming, Ont.—The Government has awarded MESSRS. P. H. SECORD & SON the contract for the erection of the court-house and registry office. The contract prices were $52,500 and $10,500 respectively.

Vegreville, Alta.—Tenders will be received up till the 4th of August, 1913, for the construction of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

Victoria, B.C.—Tenders will be received up till the 4th of August, 1913, for the erection of a school. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffith, Public Works engineer.

+—Winnipeg, Man.—The J. McDIARMID COMPANY have been awarded the contract for the new Pantages theatre. The contract price is $180,000.

+—Winnipeg, Man.—The city has awarded Mr. G. W. AIKINS the contract for the erection of a public swimming bath. The contract price is $29,000.

+—Winnipeg, Man.—The Smart-Woods, Ltd., have awarded G. H. ARCHIBALD & CO., LTD., the contract for the erection of their new building. The contract price is $200,000.

+—Winnipeg, Man.—The Metallic Roofing Company have awarded WORSWICK BROTHERS the contract for the erection of a warehouse. The contract price is $32,500.

Winnipeg, Man.—Tenders will be received up till the 4th of August, 1913, for the erection of two fire stations. Plans and specifications may be obtained from the Board of Control. M. Peterson, secretary.

+—Winnipeg, Man.—MESSRS. CARTER-HALLS & ALDINGER have been awarded the contract for the new Quebec Bank building. The contract price is $225,000.

CURRENT NEWS.

Montreal, Que.—W. H. Grant, manager of construction on the Canadian Northern Railway, east of Port Arthur, arrived in the city recently, accompanied by Colonel Greenwood, assistant chief engineer of the same division. The two have just completed a tour of inspection of all the bridges being constructed along the Canadian Northern Railway. They report that the portion around the north of Lake Superior is one of the most interesting parts of the whole road, as it traverses the famous clay belt. There are three divisions on this section, comprising a distance of 550 miles, of which 335 miles of track is completed.

Winnipeg, Man.—Construction work preliminary to the driving of the C.P.R. double-track tunnel through Rogers' Pass, B.C., at the summit of the Selkirk Range, has just begun. Plant, including excavating machinery and general supplies, is making its appearance on the scene of alterations, and the new tracks and approach cuts will be gone ahead with immediately. The work is estimated to cost in the neighborhood of $5,000,000, and will require some three and a half to complete. The tunnel is over five miles in length. The eastern portal of it will be located at Beaver Creek, and the western portal at a point below the Loops, west of Glacier Station. The tunnel will cap the mountain at a point 565 feet below the highest point attained by the existing line that crosses the Rogers' Pass divide. Two miles of track at the east end and three miles at the west end will be required leading to approach cuts, each a quarter of a mile in length. It is not likely that these cuts will be finished much before the end of the year, when the axle driving of the tunnel will be commenced. The double track approaches to the eastern portal of the tunnel will be twenty-two miles in length, but this work will not be started until next season. Excavation will be carried on both sides of the range, and both ends will be driven simultaneously. The tunnel itself will be 22 feet high and 32 feet in width, and a new type of drill known as the Leyner air drill will be used, three of which may work along side one another as permitted by the width of the tunnel. The amount to be estimated will be 250,000 cubic yards. Messrs. Foley, Welch and Stewart are the railway contractors who are undertaking the work, which will be under personal supervision of Mr. A. C. Dennis, manager for the company in Western Canada.

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade have been received:—635.—A large firm manufacturing horizontal gas engines and suction producer gas plants up to 200 H.P., wishes to appoint agents in Canada for the handling of these engines, and also of horizontal oil and petrol engines up to 25 H.P. 643.—A Liverpool firm is open to purchase railway sleepers and would be glad to hear from Canadian manufacturers of same. 649.—An Amsterdam house already representing firms in Canada wishes to obtain agencies for building materials, not conflicting with present engagements. Particulars on application. 651.—An Amsterdam firm is prepared to quote prices to Canadian importers.

The following inquiries relating to Canadian trade have been received:—657.—A firm in London, with large experience, is in a position to act as purchasing agent for Canadian firms or merchants, particularly electrical and general engineering firms. Also has facilities for representing firms engaged in the sale of hardware and soft goods. 661.—A Scotch firm inquires for quotations and samples of Canadian oils. The names of the firms making these inquiries, with their addresses, can be obtained upon application to:—"The Inquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary, and Chambre de Commerce du District du Montreal.

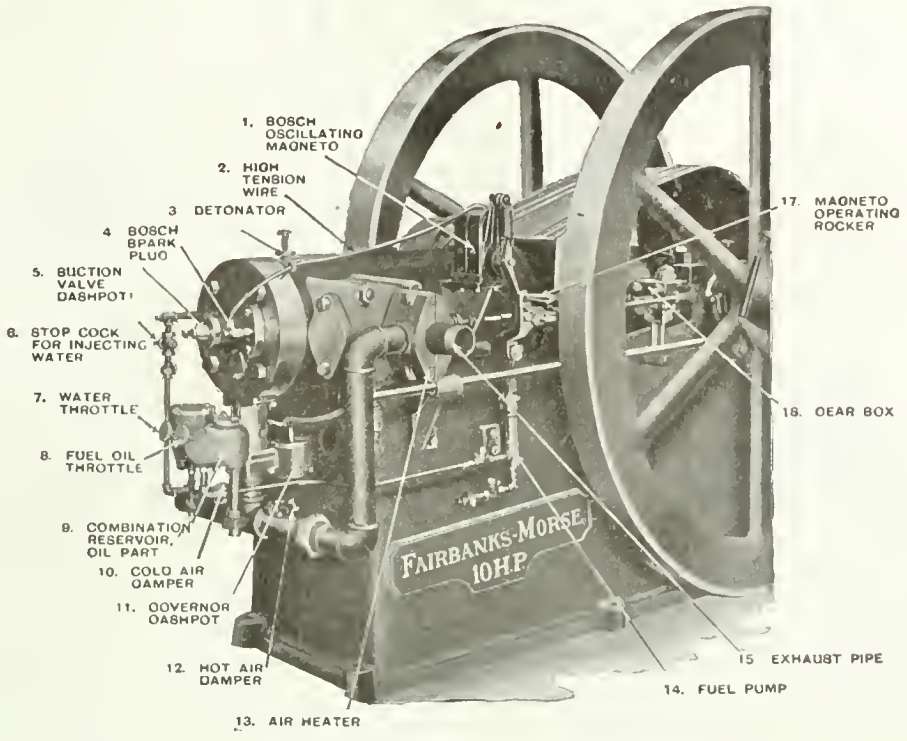
The following were among the inquiries received relating to Canadian trade at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W.:—(1) A correspondent in Belgium makes inquiry for the names of Canadian manufacturers of wood pulp, either chemical or mechanical. (2) Inquiry is made by a firm at Brussels, Belgium, for the names of Canadian exporters of timber for use in mines. (3) A Toronto firm manufacturing a liquid carbon remover for removing deposits of carbon from the cylinders of automobile and marine engines, desires to correspond with a firm of automobile accessories jobbers willing to act as their agents. (4) A north of England firm ask to be placed in communication with Canadian producers and shippers of mica.

PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Canada.—Alexander Whitton, watermarking apparatus for paper; M. Deacon and W. Gore, apparatus for mixing liquids; Oscar Dyckerdoff, metallurgical treatment of silver ores; Frank Reynolds, safety appliances for pit cages; Minerals Separation, Limited, methods and apparatus for ore concentration; William Blacker, mechanical hammer; R. H. Cox, fly trap; A. Helbronner and Max von Recklinghausen, sterilization of liquids; J. R. C. Hodgson, tire (hoop spring cushion); H. J. Moore, window conservatory; Burrell Rock Drill Co., Limited, drill chuck; W. H. J. Willson and Sydney Moody, non-puncturable pneumatic tire cover.

United States.—A. H. Welker, traction engine; Robert Gardner, apparatus for straightening wash goods before ironing; W. H. Heard, safety clutch for power pumps.



Why Use Gasoline When Oil Is Cheaper?

Especially when you can obtain a highly reliable oil engine that will develop practically as much horsepower, gallon for gallon, from cheap low grade oil as from gasoline.

As gasoline is steadily rising in price, the cost of operating a gasoline engine is becoming a serious problem. You do not have to use gasoline however. You can use oil and greatly reduce your power cost.

FAIRBANKS-MORSE OIL ENGINES

Will operate successfully on 72 per cent. of the oils distilled from the average crude. The cost of oil will continue to be low no doubt for an indefinite period, as it is claimed one oil well on an average is drilled every thirty minutes throughout the world.

As we were pioneers in the development of the gas engine, we are now the leaders in producing oil engines. **Fairbanks-Morse Oil Engines** are usually selected by those who require a thoroughly reliable engine that is economical in fuel cost and attendance, automatic in operation, safe, and easy to handle.

Another strong point in their favor is their being equipped with the famous Bosch Magneto.

The type of engine shown above is built in sizes ranging from 8 to 25 horsepower. We build oil engines in all the common sizes from 2 H.P. up to 200 H.P. Write to us for further particulars.

PLANS AND SPECIFICATIONS ON FILE.

The following plans and specifications are on file for reference only, unless otherwise noted, at the office of *The Canadian Engineer*, 62 Church Street, Toronto:—

BIDS CLOSE	NOTED IN ISSUE OF
4-8—Construction of sewers, Welland, Ontario.	24-7

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on Tuesday, August 5th, 1913, for the construction of the following sewers:—

Janet Avenue, from Lansdowne Avenue to Brown's Avenue.

Brown's Avenue, from Paton Road to 470 ft. South.

Langford Avenue, from Danforth Avenue to 1,410 ft. North.

Stanton Avenue, from Hastings Avenue to 204 ft. East.

Sawden Avenue, from Hastings Avenue to 196 ft. East.

Sproat Avenue, from Hastings Avenue to 200 ft. East.

Colina Avenue, from Eastern Avenue to Minto Avenue and Minto Avenue, from East end to West end.

Agnes Street, from University Avenue to Centre Avenue.

Berwick Avenue, from Yonge Street to 523 ft. West.

Queen Street, from 117 ft. West of Morley Avenue to 247 ft. further west.

Lane 1st E. Logan Avenue, from Victor Avenue to Simpson Avenue.

Lane 1st N. King Street, from Tecumseth Street to West end.

Lane 1st S. College Street, from Palmerston Blvd. to Markham Street.

Lane 1st W. Palmerston Blvd., from Ulster Street to Harbord Street.

Carey Road, from Cuthbert Crescent to Tullis Drive.

Belsize Drive, from Tullis Drive to Wharram Place.

Cuthbert Crescent, from Belsize Drive to Manor Road.

Manor Road, from Tullis Drive to 54 ft. E of Servington Crescent.

Carlaw Avenue Storm Sewer, section No. 2.

Bracondale Hill Road, from Davenport Road to Turner Road.

Glenholme Drive, from Clendennan Avenue to Fairview Avenue.

Colbeck Avenue, from Runnymede Road to Jane Street.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen and forms of tender obtained at the office of the Commissioner of Works, Toronto.

Tenderers shall submit with their tender, the names of two sureties (approved of by the City Treasurer, not members of the City Council or officers of the Corporation of the City of Toronto), or in lieu of said sureties, the bond of a Guarantee Company approved as aforesaid.

The usual conditions relating to tendering as prescribed by City By-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

Toronto, July 23rd, 1913.

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on Tuesday, 19th August, 1913, for the construction of the following works:—

When designing

structures do you pay sufficient attention to the various matters that govern insurance ratings?

Not only can you add greatly to the fireproofness of buildings by adopting our suggestions, but it is very likely that you can do so without the improvements costing anything ultimately. They will be paid for by the lower insurance rates.

Correspondence solicited. We have a staff of engineers and inspectors trained in this highly specialized line. Make use of our services.

In making sewer pipe

many pieces come from the kilns with imperfections. They are rendered imperfect by having pieces broken out of the socket or spigot end, or having fire cracks at either end or extending partly through the body of of the pipe. Or they may be imperfect in shape, out of round or not straight; not thoroughly vitrified or glazed; or with blisters or scales blown off the outside. Such pieces cannot be classed as strictly first-class pipe. When buying pipe from us one can rest assured that we will never deliver pipe with imperfections such as above unless "seconds" are particularly asked for by the purchaser.

MONTREAL

SECOND EDITION, Revised

WEBB—**Economics of Railroad Construction.**

By Walter Loring Webb, C.E. Small 8vo, viii+339 pages. 34 figures. Cloth, $2.50.

The preparation of this edition has required a very extensive revision and even the rewriting of revised tables in order to make the computations correspond with the classification of operating expenses now used by the Interstate Commerce Commission.

FIFTH EDITION, Revised and Enlarged

WEBB—**Railroad Construction.**

By Walter Loring Webb, C.E. 16mo, xvii + 767 pages, 217 figures. Morocco, $4.00 net.

In this edition the author has made all recommendations pertaining to construction work to conform with the most recent recommendations on these points suggested by the American Railway Engineering Association, who granted him special permission.

FISH—**Earthwork Haul and Overhaul.**

By J. C. L. Fish, Mem. Amer. Soc. C.E., Professor of Railroad Engineering, Leland Stanford Junior University. 8vo, xiv + 165 pages, 66 figures. Cloth, $1.50 net.

Presents answers to all questions on computation of overhaul, and on the use of the mass curve in planning distribution. Includes the discriptions of bases and methods of computation of overhaul which bring about a definite understanding with railroad engineers as to the way in which the overhaul is to be computed.

ORROCK—**Railroad Structures and Estimates.**

By J. W. Orrock, C.E., Structural Engineer. 8vo, vi + 270 pages, 93 figures. Cloth, $3.00 net.

Covers in brief and concise form the numerous subjects that enter into the engineer's estimates of railroad building.

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned and endorsed "Tender for Public Building, Sudbury, Ont.," will be received at this office until 4.00 P.M., on Wednesday, August 6, 1913, for the work mentioned.

Plans, specification and forms of contract can be seen and forms of tender obtained at the office of Mr. Thos. Hastings, Clerk of Works, Postal Station "F," Yonge St., Toronto, at the Post Office, Sudbury, Ont., and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to five per cent. (5%) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, July 16, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—45139.

TENDERS FOR THE CONSTRUCTION OF SEWERS.

Sealed tenders will be received by Mr. C. M. Webber, Town Clerk, Welland, Ontario, up to 5 p.m. on Monday, 4th August, 1913, for the construction of Separate Sewers on the following streets:—

Maple Avenue; William Street; Oakland Avenue; Asher Street; River Road; Duncan Street; Cady Street; John Street.

Specifications and tender forms may be had at Engineer's Office, Welland. Plans and specifications may also be seen at the office of *The Canadian Engineer*, 62 Church Street, Toronto, on or after 25th instant.

A marked cheque for 10 per cent. of the amount of the tender must accompany each tender, or an acceptable bidder's bond of same value will be accepted.

The lowest or any tender not necessarily accepted. The tenders may be awarded separate or in bulk.

JAMES HUGHES,
Chairman Sewerage Committee.

Welland, July 22nd, 1913.

TENDERS FOR BRIDGE CONSTRUCTION.

Sealed Tenders plainly marked as to contents will be received by the undersigned up to NOON of WEDNESDAY, AUGUST 6th, 1913, for the construction of a reinforced concrete culvert on Yonge Street, at Langstaff, opposite Lot 36, Markham, in the County of York.

Plans and specifications and all necessary information may be seen at the office of the undersigned, 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER.
County Engineer.

Toronto, July 22nd, 1913.

TENDERS FOR BREAKWATERS.

SEALED TENDERS, plainly marked as to contents, will be received by the undersigned up to 6 p.m. of **Monday, August 11th, 1913,** for the construction of:—

1. Breakwater at the north-east corner of Lambton Mills Bridge, on Dundas Street, over Humber River.

2. Breakwater at north-east corner of Scarlett Road Bridge over the Humber River.

Plans and specifications and all necessary information may be obtained at the office of the undersigned, 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
County Engineer.

Toronto, July 30th, 1913.

(For further tenders see page 84).

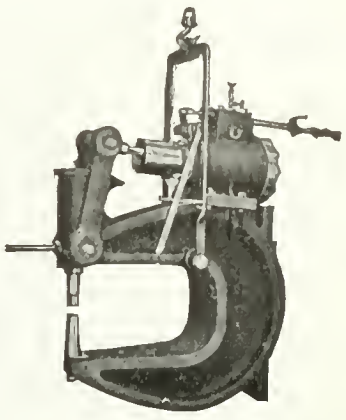
Whatever the Riveting — there's an "ALLEN" for the Job



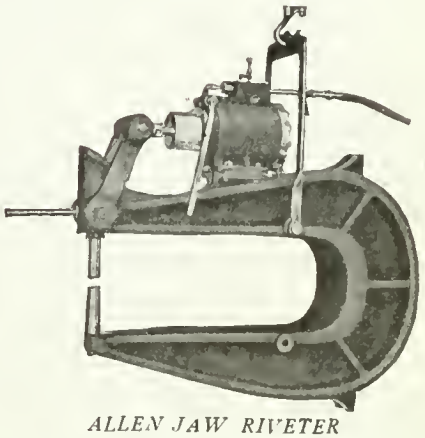
ALLEN JAW RIVETER

Allen "Jaw" Riveter

This riveter is most suitable for all descriptions of bridge and building construction work. By a special patented device any desired change in the distance between the dies is easily effected.

Allen "Alligator" Riveter

This riveter is especially adapted for all types of steel car construction riveting work. Suspended on a double axis, machines of this pattern can be arranged in any position, thus making them indispensable for work of this character.



ALLEN JAW RIVETER

Allen "Compression Lever" Riveter

This riveter is built expressly for heavy bridge, beam and girder work and is widely used for this purpose.

Allen "Stake" Riveter

This riveter is built expressly for close channel column work where flanges are turned in and measures only 3¾ inches at the widest section of stake.

Allen "Boiler" Riveter

This riveter is built expressly for boilers, tanks, stacks, etc., and may be constructed with any desired distance between arms.

Merit is built into every part of these machines and if you use them you may be sure of the FASTEST and TIGHTEST riveting at the LOWEST cost.

Special Riveters to meet all Requirements

SECOND-HAND MACHINERY

Second Hand Contractors' Machinery

Why not use second hand equipment on the next job? We have a large stock of machinery ready for delivery

Nearly Good as New

Get the details on these items:—
1—24" x 24¼" x 30" "Ingersoll-Sergeant" compressor, Class A
1—20" x 20¼" x 24" "Ingersoll-Sergeant" compressor, Class A
1—14" x 14¼" x 18" "Ingersoll-Sergeant" compressor, Class A
1—No. 2½ "Smith" concrete mixer
1—No. 5 "Gates" gyratory crusher, style K
1—30" x 14" "Buchanan" crushing roll
1—35 H.P. "Farquhar" combined engine and boiler
2—No. 15 "Morris" centrifugal pumps with engines

L. F. SEYFERTS' SONS, Inc.
437 NORTH THIRD ST., PHILADELPHIA, U.S.A.

FOR SALE—almost new, differential tackle and track; carry two tons. Canada representatives, 193 Spadina Avenue, Toronto.

FOR SALE—almost new, two 700-gallon cypress wood tanks with fittings, and 4 one hundred-gallon tanks on castors. Canada representatives, 193 Spadina Avenue, Toronto.

FOR SALE.—Complete Sewer and Water Contractor's outfit, including one Parsons' Trench Excavator, Trench Braces, Fire Pots, Pumps, etc. For price and terms apply to Navin Bros., Contractors, Moose Jaw, Sask.

FOR SALE at a snap: 60-H.P. Cowan and Co. engine and 80-H.P. Cowan and Co. boiler. Write for particulars, J. F. Barnard and Son, Spencerville, Ont.

CORLISS ENGINE—16 x 36—new two years ago; very reasonable. Box 82, *The Canadian Engineer*, Toronto.

FOR SALE.—Steam Barge, sand dredge, 2 deck scows, 1 barge. For full particulars apply to Box 88, *The Canadian Engineer*, Toronto.

FOR SALE.—3 second-hand contractor's Dinky Vulcan Locomotives in first-rate condition. One 9 in. x 14 in. and two 10 in. x 16 in. Also a 50-ton Steam Shovel, and some contractor's Dump Cars. Apply to The Canadian Fairbanks-Morse Co., Limited, 444 St. James St., Montreal.

WANTED.—A second-hand centrifugal pump, 6,000 to 10,000 gallons capacity, electric motor or gasoline driven, direct connected. Address Box 90, *The Canadian Engineer*, Toronto.

PILING WANTED—Forty pieces of second-hand steel sheet piling, about 20 to 22 feet in length. Address Box 94, *The Canadian Engineer*, Toronto.

"PITTSBURGH" STEAM SHOVEL DIPPER TEETH and Attachments (Canadian patent dated August 22nd, 1911), for sale by Standard Steel Construction Company, Welland, Ontario, Canada.

NEW INCORPORATIONS.

Munson, Alta.—Wilsons Limited, $50,000.

Burton, B.C.—Arrow Lakes Cannery Company, $10,000.

North Vancouver, B.C.—North Shore Coal Company, $25,000.

Samsonton, Alta.—Crossfield and Samsonton Mutual Telephone Company, $3,000.

Fort William, Ont.—Varlow Foundries, $40,000. H. J. Varlow, C. Varlow, C. Gray.

Galt, Ont.—Canadian Motors Company, $40,000. G. A. Dobbie, F. S. Scott, E. J. Getty.

Cobalt, Ont.—Sharon Mines, $500,000. R. H. Parmenter, A. J. Thomson, W. S. Morlock.

Redcliff, Alta.—Brittain-Plewes Company, $40,000. Redcliff Construction Company, $40,000.

Ottawa, Ont.—Langford-Feldheim, $40,000. W. Y. Bennison, E. F. Holcombe, J. H. Barker.

Vancouver, B.C.—Dominion Iron Works, $50,000. Farr Brass Manufacturing Company, $50,000.

Lethbridge, Alta.—Lethbridge Industrials, $25,000. E. T. Broad Contracting Company, $25,000.

Tofield, Alta.—Tofield Foundry and Machine Company, $50,000. Dominion Brick Company, $10,000.

Edmonton, Alta.—Edmonton Pure Water Company, $25,000. Fraser Wright Coal Company, $250,000.

Ruthven, Ont.—Ruthven Cold Storage and Forwarding Company, $40,000. M. Whaley, C. R. Wigle, G. Fox.

Hamilton, Ont.—Artisan Land and building Company, $100,000. J. W. Gage, J. W. Bonsfield, G. Boulter.

Napinka, Man.—Napinka Manufacturing Company, $60,000. W. N. Crowell, W. J. Ronoghan, H. D. Yeomans.

The Pas, Man.—Mineral Point, $75,000. W. H. Morrow, V. W. Inglis, W. Bartholomew, both of Winnipeg.

Sault Ste. Marie, Ont.—Andrews Lumber Company, $150,000. J. R. Andrews, H. R. Andrews, I. C. Jennings.

London, Ont.—Dominion Metal Specialities Manufacturing Company, $40,000. C. E. Santo, J. S. Ferguson, B. L. Santo.

Winnipeg, Man.—Commercial Power, Light and Coal Company, $250,000. F. M. Burbidge, R. C. McPherson, R. W. Killey.

Roxton Falls, Que.—Roxton Concrete, $45,000. F. Dieulefet, Farnham, W. Poirier, J. H. Provost, both of Roxton Falls.

Montreal, Que.—Administration and General Construction Company, $100,000. P. Bonhomme, G. Bonhomme, J. B. Bonhomme.

Calgary, Alta.—Calgary Sand and Gravel Company, $10,000. North Western Engineering and Construction Company, $15,000. Cullon Patent Manufacturing Company, $10,000.

Toronto, Ont.—International Steel Corporation, Ltd., $100,000. D. A. MacRae, T. W. Lawson, H. E. McKitrick. Canadian Oil and Fuel Company, $10,000. A. J. Reid, R. H. Montague Temple, W. L. Pinkney. Premier Mica, $50,000. W. J. Morrison, J. Legault, H. J. Baldwin. Sutherland-Davey, $50,000 (marble dealers). C. F. Ritchie, J. H. Oldham, A. E. Knox. Crow Lake Ironclad Company, $100,000. F. Smith, Elk Rapids, W. F. Bowen, Mamora, J. Parker, Toronto. J. H. Sherrard Manufacturing Company, $1,750,000. A. J. Thomson, W. S. Morlock, N. B. Wormwith. Re-enforced Concrete Post Company, $50,000. G. Cooper, W. K. Fraser, F. A. A. Campbell. Progressive Builders, $200,000. E. C. Ironside, W. J. McLarty, C. M. Brearley.

The only building material that has not increased in price is

CANADA Portland CEMENT

It makes concrete that can be depended upon for satisfactory results, whether used for bridges or for foundation-piers.

Canadian architects and engineers have confidence in the uniformity of Canada Cement.

They know that—by reason of our twelve mills all working under the same conditions—they can get the same high quality now or in the future as they obtained in the past—the same high quality no matter in what part of Canada the work is undertaken.

The Western Canada Irrigation Association will hold its seventh annual Convention in Lethbridge, August 5th, 6th and 7th. An excellent programme has been arranged, including fifteen papers by prominent irrigation men, based upon the value of such work and the up-to-date methods in use in Western Canada and the United States. Delegations from the large Irrigation Congresses in the Western States will be in attendance. The president of the Association is the Hon. Duncan Marshall, Minister of Agriculture, Alberta; the secretary, Mr. Norman S. Rankin, Calgary. A notable feature of the literature of the association is the epigram "Intelligent men no longer pray for rain—they pay for it."

The contract for the first section of the new Welland Canal has been let by the government to the Dominion Dredging Company at three and a half million dollars, the lowest tender. This is for section one of the new canal, beginning at Lake Ontario. It is the intention of the government to let the contracts for the work section by section. The new canal is to be finished in five years, and will cost approximately fifty million dollars. Work on section one will be commenced at once by the successful tenderers.

W. H. Allen, Son and Company, of Bedford, England, engineers and builders of steam, hydraulic and direct current electric machinery, are open for negotiation with a reliable firm to act as agents for Canadian business. The company's direct representative in Canada is Mr. A. Leo Mieville, who can be addressed care of Box 92, *The Canadian Engineer* Office, Toronto.

MARKET CONDITIONS

Montreal, July 26th, 1913.

Prices hold very steady, being again unchanged, as follows:—

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is unchanged, being now per 100 lbs., as follows:—¼-in., $5.30; 5-16-in., $4.70; ⅜-in., $3.90; 7-16-in., $3.65; ½-10., $3.55; 9-16-in., $3.45; ⅝-in., $3.40; ¾-in., $3.35; ⅞-in., $3.35; 1-in., $3.35.

Copper.—Prices are 16¾c. Excellent demand.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are: Queen's Head, $4.35; Colborne Crown, $4.25; Apollo, 10¾ oz., $4.25. Add 25c. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lead.—Prices are firm at $5.35.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is active and strong:—$36 for 6 and 8-inch pipe and larger; $37 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 73½ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73½ per cent. for black and 63½ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, July 30th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—¼-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound, 1 to 9-case lots, 50 lbs to case. For each additional in per cent. nitro-glycerine add 1¼c. per hundred. For 10-case lots and over deduct ¼ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1¼ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ⅝-inch, $3.45; ¾-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $6, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.20; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, July 29th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. plts, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.25; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

A weekly paper for engineers and engineering-contractors

NOTES ON TUNNELLING FOR SEWERS

SOME INSTANCES INVOLVING DIFFICULT CONSTRUCTION THROUGH UNFAVORABLE GROUND — IMPROVISED METHODS TO COPE WITH UNSTABLE SOIL, HEAVY SURFACE TRAFFIC, ETC., MEETING WITH SUCCESS.

By J. M. M. GREIG, A.M.I.C.E.

IN the laying of sewers, according as the ground varies so must the systems of placing temporary and permanent support be changed to meet the particular conditions. It has been the author's good fortune to be connected with tunnels driven through all gradations of stability, from hard rock, shale and boulder clay down to glacial mud and quicksand. In the firmer ground the usual methods, such as top heading with crown bars, cap and leg, and so on, were adopted with brickwork and concrete as the permanent lining of the tunnel, but more difficult circumstances necessitated other means.

The low-level intercepting sewers of Glasgow were almost all near, and parallel to, the River Clyde, and on a grade below high tide level, while in the streets along which they passed there was very heavy traffic. In this case, when unstable ground was met with, a permanent construction of cast iron segments with a finishing inside lining of concrete was adopted.

Iron Segments or "Plates."—This form of cast iron tunnel is shown in Fig. 1, and sewers from 3 ft. 6 in. to 9 ft. in diameter were built of these "plates." Each tunnel ring measured 1 ft. 6 in. in length, and consisted of five or seven plates and a key, all having 5-inch flanges; the lower plates having radial flanges and the two upper ones each a non-radial flange to admit of the key being pushed up from below. The key had parallel flanges. The metal was ¾ in. thick and the flanges 1 in. thick, stiffened with feathers cast between the bolt holes. Both the plates and the key had a 1-in. diameter hole in the centre, to admit grout under pressure. The horizontal and vertical flanges had a fillet 1½ in. wide and ⅛ in. thick cast on the outer edge to form a joint of iron to iron. In the space, ¼ in. by 3⅞ in., between the flanges a slip of white pine ⅜ in. thick was placed, and as the bolts were tightened up this was compressed, forming a fairly close joint. All joints were bolted with 1 in. diameter bolts having hexagon nuts and a grummet of tarred string below each washer at the head and nut. Oak wedges 2½ in. by 2 in. were driven into the white pine packing at all joints which leaked, serving well the purpose of stopping these leaks.

On curves of sharp radius (50 feet) special radiated rings were used, but on those of flat radius the necessary curvature was obtained by double packing the outer side of the curve; or, if this gave the iron too great a lead, a strip of felt was used. Longer bolts were required on curves. Felt was also used to raise or depress the rings, and with double packings on curves a good deal of adjustment was necessary to keep the tunnel to gradient.

Excavation in Glacial and Mud.—This clay was of a brownish grey color, very finely divided, entirely free from stones or grit, and very uniform except as to the amount of water it contained. It varied a little in toughness, but in no case could it be got to drain. When freshly cut, this clay would stand for a very short time

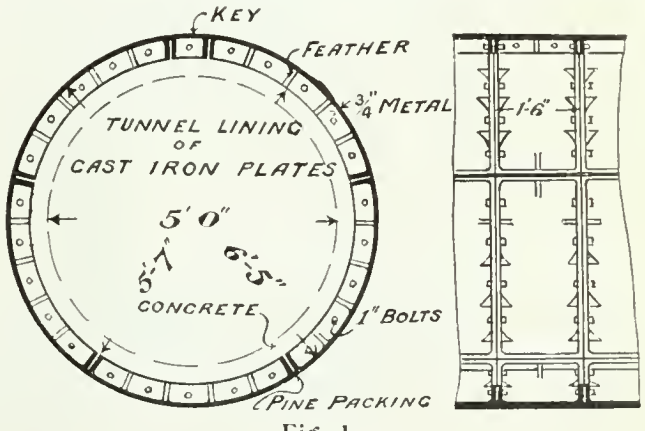

Fig. 1.

with a narrow face, five or six feet in height, but with exposure to air or the slightest amount of working, it became a tough slurry into which the miners sank to knees.

At the start of one section (5-ft. sewer) the miners, not being familiar with the good points of iron rings, attempted to take out a length of 9 feet on timbers instead of opening out ground for one ring at a time. The result was most unsatisfactory. It took them four or five days to get out a length, while a great deal of timber was used and unnecessary excavation removed, causing surface subsidence with a cover of 20 feet. The miners next tried a shorter length, sufficient excavation for two rings only being taken out, and the working conditions improved considerably, much lighter timber being used. After tak-

ing out a few lengths in this fashion it was found that, by excavating 1 ft. 6 in. forward and building up a ring at once the face would stand with little or no timbering, whereupon the rate of progress increased from 9 ft. to 40 ft. per face per week, and in one case 66 feet of iron was placed in one face in a week, of course, working night and day. In tunnelling this clay, the important point was to keep the face constantly moving as exposure to the air or unnecessary vibration converted it into mud, so fine that it ran through between the poling boards where a knife blade would not go.

The miners, when working for one ring, did not require to stand on the clay at all, which kept it in a fairly stiff condition in the bottom.

length of open-cut long enough to construct air locks in, it was necessary to drive sheet piles, 6 inches thickness, well below formation all round, and to pole the bottom throughout. Within the piling two lengths of sewer were built each way off a centre opening, and air-tight doors, etc., were built in to form air locks for driving the tunnels in both directions. Before filling in above these lengths, the piles which crossed the line of sewer were bored off about top level of tunnel, and horizontal piles were driven in to form a roof for the miners breaking away, and to prevent, if possible, escape of air up the sides of the vertical piles.

This was quite effective and no trouble was experienced in breaking away from the open-cut. With suf-

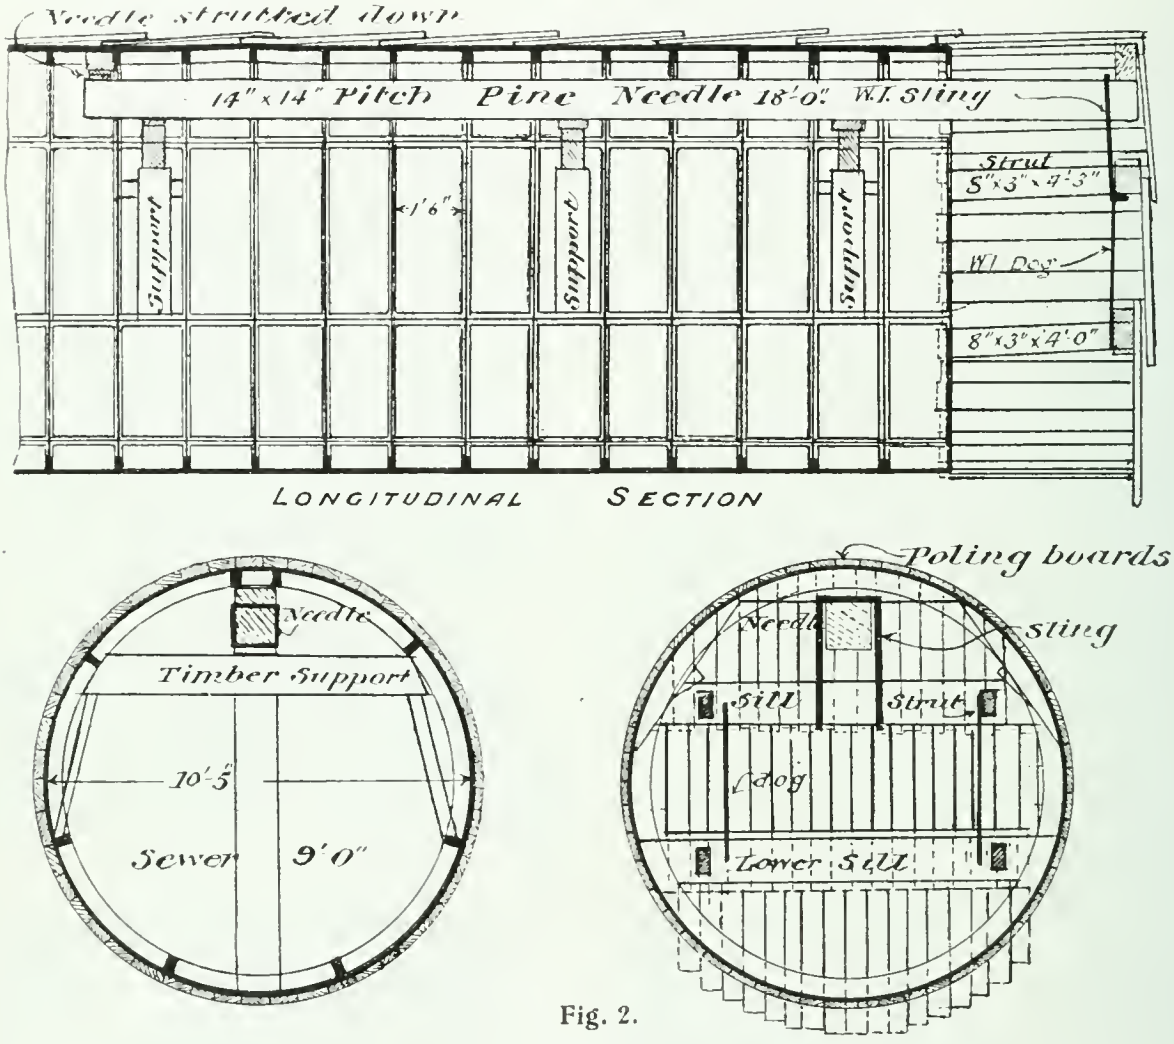

Fig. 2.

On another sewer, 9 ft. diameter, where the ground was getting very near to a condition necessitating air pressure, a considerable length of tunnel was driven by timbering for two rings at a time, with the entire face constantly close poled. Here, however, a difficulty arose through the weight of ground carried, by the end ring giving it a dip. To get over this the "needle" shown in Fig. 2 was used. As soon as the upper part of the face was excavated this "needle" was thrust forward, transferring the weight back to the second ring instead of on the leading one. This arrangement turned seeming failure to success.

About half a mile of this 9-foot sewer was through ground too unstable for any method but that with compressed air. In fact, to get down to grade and form a ficient air pressure to keep the face dry there was no difficulty in completing this tunnel and good progress was made. The effect of air pressure on the ground all round was remarkable.

Previous to going in for air pressure a narrow shaft had been sunk, with great difficulty, in the neighborhood, the ground being so soft that planks 9 in. by 3 in. and 12 ft. long. were driven to the head with a hand maul. When later it was necessary to sink onto the completed tunnel for a manhole, the ground which had been subjected to air pressure was dry and stiff, so that little timbering was required in sinking.

With air pressure and cast iron segments there is not much difficulty in tunnelling through this clay, so long as it is not so liquid as to refuse to support the

weight of the finished sewer. Of course, if the tunnel is of considerable diameter there is difficulty in a pressure sufficient to keep the bottom in place being too strong for the top and causing blow-outs and a general lowering of pressure. This is more apt to occur in sand, however, and it may then be necessary to use a shield with separate compartments.

Tunnelling in Sand and Gravel.—In another instance about 1,500 feet of 4-foot diameter sewer lay below a street along which ran four lines of rails. Several engineering works had frontage on these streets and much heavy freight traffic passed along the rails. Coarse sand and gravel containing a varying quantity of mud was found here, but although much charged with water, it drained freely. Undoubtedly this ground would have lent itself to cap-and-leg tunnelling had it not been for the hammering action of the trains above a cover of 15 feet. A brick-lined tunnel would have necessitated dependence on the timbering alone for too great a time, and in consideration of the danger to traffic that might arise through any subsidence, it was decided to build the sewer in iron.

A great quantity of water drained into the tunnel and in places the gravel was overlaid with a bed of earthy mud containing decayed vegetable matter. This loose top became exceedingly troublesome during a spell of very wet weather, and to combat the difficulties it presented the method of timbering shown in Fig. 3 was adopted. The peculiarity of this system lies in the iron rib used as a temporary support for the head piles.

Assuming the length has been taken out for two rings, the procedure is as follows: The three lower plates for two rings are bolted in position and the piles are driven over the iron rib under the cross-head tree and raking side trees round the top. The remaining plates of the two rings are keyed up, the leading ring gripping the ends of the piles and thus relieving the rib which may then be taken down. One face leg at a time can now be taken down and, after excavation, re-erected on a foot block under shelter of the piles. The lower half may be either poled circularly with horizontal boards or piled vertically.

Erection of Iron.—As all plates weighed about 300 pounds, or under, no difficulty was experienced in handling them and no special appliances were used. In getting in the key it was usual to put the upper plates in position and, while they were lightly held by their bolts, a screw jack 8 in. long was inserted in the key space and used to press them outwards. Then they were bolted tightly and, on withdrawing the jack, the key could be pushed up from below. By easing the upper plate bolts these plates came inwards and gripped the key when all bolts could be tightened up. Each wooden packing slip was tied to its flange by strings through the bolt holes to keep it in position till in place.

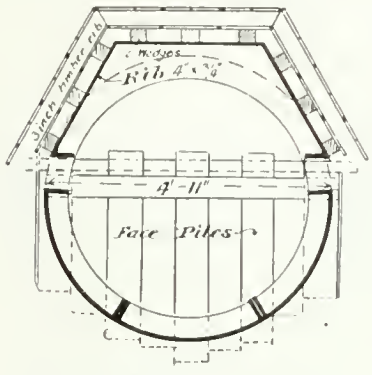
Pressure Grouting.—After erecting from eight to ten rings the face was poled up while these rings were grouted with lime under a pneumatic pressure of from 30 to 40 pounds per square inch. Air for grouting was supplied by small compressors used for this purpose alone. The usual type of grouting pan with paddles was used, its diameter being 1 ft. 6 in. and its overall length 3 ft.

In small tunnels a very low truck or bogie should be provided for the pan, to give free room above for filling in lime quickly as it is important to do this with all speed, for the lime that was used set very quickly.

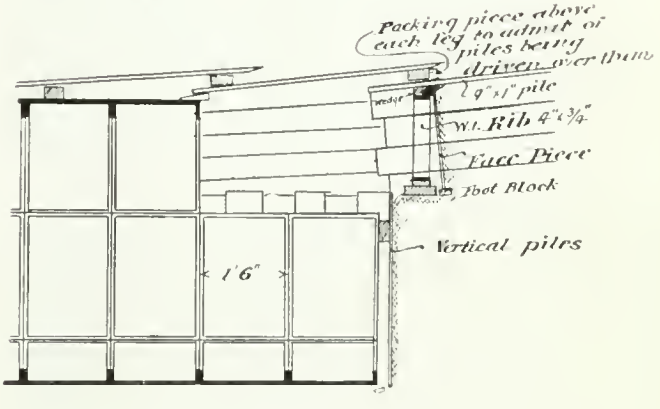
The quantity of lime varied very much, according to the ground and the method of tunnelling it.

In grouting rings 6 ft. 5 in. diameter which had been driven through clay with timbering, only two to four bags of lime were necessary, but no less than eight were used for each ring (5 ft. 5 in. external diameter) in the timbered excavation through sand and gravel. As all water from the face drained over the lower plate to the shaft, it was difficult to locate open joints before grouting, and a certain quantity of grout found its way back into the tunnel through the lower joints.

Lining With Concrete and Granolithic.—When the tunnels had been driven through from shaft to shaft, all dirt was removed from between the flanges. This, of course, meant lifting and re-laying the rails.



ELEVATION OF FACE



LONGITUDINAL SECTION

Fig. 3.

The lining concrete consisted of one part cement, two parts sand, and one part whinstone or chert, broken to pass through a 1¼-inch diameter ring.

Starting from a point midway between two shafts, the bottom plate was fitted, the road being lifted but not the rails. This occupied a few days, by which time the concrete in the mid-length had set hard. A length of rails (12 feet) was lifted at the mid-point and fresh concrete laid on, bringing the surface up to 1 inch below water-run. Laggings 3 inches thick were laid upon this, and circular iron ribs erected on these laggings, the ribs being kept in position by distance pieces from the flanges. Above the bottom plate concrete was packed in as each lagging was run in from the end, until the key was reached, when block laggings were used, the latter being of varying width, to give greater freedom at cross-flanges. The block laggings were 1 ft. 6 ins. long and were placed transversely to the axis of the tunnel and rested on the two last longitudinal laggings which were grooved to receive them.

This method was very successful, there being but few defects or vacant spaces in the concrete when the

laggings were removed. As a rule, the concrete was allowed to set for two days before striking the ribs.

Granolithic.—Granolithic, consisting of one part cement and one part finely ground granite dust, was used to form the finished invert. On the arch a little sand was mixed with the granite (about one of sand and three of granite) to toughen the granolithic and give it a smoother finish. The total thickness of one inch was put on in three layers, without the use of centering, the last layer being polished with plasterers' tools. Nails were driven in the concrete at springer level by the engineers, every ten feet, and a light strut was fixed with wedges to this level by the plasterers. Then, with a centre on this piece an arm was used to sweep out the finished circle of the sewer.

The plasterers made a narrow fillet of cement at each length to the finished diameter and, after these had set, used them as profiles to test their work with a straight-edge. A part of the invert, 1 ft. 6 in. wide, was left unfinished until the entire length from shaft to shaft had been lined, when fresh levels were given on the invert by forming fillets across the 1-ft. 6-in. space at each 10-foot length. This method gave the men a space to stand on while working the sides, and ensured the absence of traffic while the invert was setting.

The concrete and granolithic proved quite effective in stopping any leakage left in the iron joints, and formed a water-tight sewer with a hard and smooth invert.

The writer had occasion to remove a portion of sewer constructed similarly to the above which had been in position for a dozen years or more. In it the concrete lining was exceedingly hard and smooth, while the iron segments completely retained their black coating. The sewage had had no effect upon the granolithic beyond forming a slimy skin upon it.

CANADIAN IMPORTATIONS OF STONE.

The imports of stone are classified as building stone of all kinds, except marble, manufactures of granite and other stone, and marble and its manufactures. The total value of the imports during the calendar year 1911, according to statistics contained in the annual report on mineral production in Canada by J. McLeish, B.A., was $1,140,846, as compared with a value of $845,123 in 1910, showing an increase of $295,723, or about 35 per cent. Of the total imports in 1911, $392,868 in value was classed as building stone, and included 21,356 tons of rough stone, valued at about $3.98 per ton, and 52,908 tons of dressed stone, valued at about $5.82 per ton. The imports of sawn granite, manufactures of granite, and manufactures of stone N.O.P., were valued at $207,836; paving blocks, $64,676; marble and manufactures of, $384,252. There was also an importation of refuse stone of 226,122 tons, valued at $91,214.

During 1910 the imports of building stone were $311,595; manufactured granite, $192,213; paving blocks, $74,100, and marble, $267,215. The imports during both years were derived chiefly from the United States and Great Britain, the United States supplying building stone, paving blocks, and marble principally, and Great Britain mainly manufactures of granite. Marble is obtained in some quantity also from Italy and other countries. The total value of the imports from the United States in 1911 was $946,624; from Great Britain, $175,169; from Italy, $6,334, and from other countries, $12,719.

The value of the imports from the United States in 1910 was $640,084; from Great Britain, $160,664; from Italy, $31,314, and from other countries, $13,061.

OPPORTUNITIES FOR HIGHWAY ENGINEERING IN CONTRACTORS' ORGANIZATION.

By H. B. Pullar, A. M. Am. Soc. C.E.

THE recent rapid development of paving and road building has opened up a new demand for engineers, and this new demand must be filled by engineers trained along new and specific lines. Until recently a general civil engineering course amply prepared an engineer with sufficient knowledge to take care of any general road or paving work which might come under his supervision, but in this day of specialization it is necessary that engineers entering into this new field be more carefully prepared to successfully meet and solve the numerous and varied paving problems and direct to the best advantage the enormous fund now being appropriated for good roads and pavements. An enumeration of a few of the problems with which a paving contractor has continually to contend, and the place waiting for the highway engineer with respect to their proper solution, are pointed out in Mr. Pullar's paper before the Society for the Promotion of Engineering Education at its convention in Minneapolis in June.

Formerly an engineer desiring to specialize in road and pavement construction was limited in his field of endeavor to accepting positions with the state, county or city, or to act as a consulting engineer to public officials having charge of paving and road work. To-day there is a much broader field, and one in which the opportunities for advancement and the compensation are much greater than they were even a few years ago. This field is the up-to-date contractors' organization. There is a distinct and urgent demand for good highway engineers in contractors' organizations, and the day does not seem to be far distant when public officials will demand that work be given only to contractors having a capable and efficient organization, which necessarily must include a highway engineer.

Practically up until the present time there has never been a demand for highway engineers by contractors, because there were only a few different standard types of pavements and the contractors were familiar with the classes of construction they bid upon and did not attempt to enter into other fields. To-day the problem is entirely different, and in place of the few standard types of pavements and roads there are numerous and varied types which call for different construction.

In nearly every case where contractors to-day wish to bid on paving construction they are confronted with specifications calling for numerous different types of construction. They have not always been educated into the proper method of laying these different classes of pavements, but are usually willing to take a chance, and the result has been that there have been many failures, which have been due to improper handling of materials and improper construction, but which have been unjustly blamed to the new type of pavement or road. As is always the case when any industry is rapidly developing, there are also many new types of paving, both patented and otherwise, which are continually being brought upon the market, some of which will undoubtedly prove a success, but as usual the majority will soon be discarded as being unsuccessful and unsatisfactory.

With the advent of the highway engineer into the contractors' organization, a great per cent. of failures will be eliminated, for if he is properly trained he will be

versed in the different types of construction and will be able to get the best results with the materials with which he must work. He will be able to advise and assist the contractor in developing new and more up-to-date construction, and guard him against taking too many chances. He will, from his training, more carefully look after the details of construction, such as drainage, grades, fills and crowns of the finished roadway, all of which at the present time are given too little consideration by contractors. In case of apparent failure of the work his training will teach him to look for the real cause and not blame it haphazardly upon the new type of construction or on the binding material, such as has been too often the case.

It does not cost a contractor any more to lay high-grade, first-class work than it does to put in careless and unsatisfactory work; in fact, the cost of inefficiency and carelessness in running a great many of the contractors' plants throughout the country would more than offset the cost of turning out uniform and high-grade pavements. The properly trained highway engineer will see these different points and by actual demonstration show the contractor where he can lower his maintenance cost and at the same time give better satisfaction to the officials and property owners. By his work he will eventually be a big factor in eliminating the now too well recognized combination of politics and graft in paving and roadway construction.

Already a number of the most successful and prominent contractors in the country are employing men trained in highway construction and have found it both wise and economical to have these men in their organization to pass upon and keep uniform all details of construction which have heretofore been left to the superintendent and plant foreman.

There is another potent reason why contractors will require the services of highway engineers. It is the fact that on account of the severe competition and rapid development of the road and paving industry, material companies are continually putting out new products and changing the old. It is only fair to state that most of these material companies are doing their utmost to turn out the best possible material for the money. They are, without question, giving valuable co-operation to engineers and chemists in order to get the most suitable materials for the different types of construction and are continually studying and overcoming the problem of paving and road building. However, even in view of these facts, it is a big advantage for any contractor to have in his organization a highway engineer who will study the different traffic, climatic and other conditions under which the pavements or road will be subjected, and then be able to judge those materials which are most likely to prove suitable for the work. He will also be able to advise regarding the proper handling of these different materials, or at least to look for and properly receive expert advice regarding them.

There are few bituminous materials on the market to-day that require the same treatment at the plant in order to get the best results at the lowest possible cost; in fact, numerous failures can be cited where the cause was due to the handling of different materials at the paving plant in the same manner.

While the highway engineer in the contractors' organization will likely find his work for some time confined to estimating and to the actual construction, he will in time prove a valuable asset in the promotion work

There will be many obstacles to overcome by the highway engineer entering such a field. He will have to proceed with his new ideas and methods in a slow but sure way and use his technical knowledge in a practical and efficient manner, but if he has received a proper academic training he cannot help but be of value to the contractor, and will find each year an increased demand for his services. It would be well if universities and engineering colleges consider the advisability of incorporating a three-hour-year course devoted to highway engineering in their undergraduate courses in civil engineering in order that engineering graduates may have a broad general knowledge of that important field.

A LARGE POWER STATION.

Work has been started on the hydro-electric power station of the Cedar Rapids Manufacturing and Power Company, Montreal, Que., which, when completed, will be the largest in the Dominion of Canada. Its initial rating will be about 100,000 horse-power, and later on this will be increased to 160,000 horse-power. The site is at Cedar Rapids, in the St. Lawrence River, about 30 miles above Montreal.

The plant will be 663 ft. long and 130 ft. wide, and will be built as a part of the dam. The intakes will be of the scroll or involute type. Orders have been placed by the Cedar Rapids Company for the generating equipment. This includes twelve 10,800 horse-power waterwheels, which are to operate at 56 r.p.m. under a head of 30 ft., and will be the largest ever built. There will also be three 1,500 horse-power exciter units, which will operate under the same head as 150 r.p.m. Twelve generators are to be connected to the waterwheels.

The design of the turbines possess an interesting feature in the arrangment for carrying the weight of the generator rotor and the moving parts of the turbine on a thrust bearing above the generator instead of below, as is often done. The waterwheel contract includes the turbine complete, the shaft running through the turbine and generator, the thrust-bearing support or truss to be located above the generator, also the thrust bearing complete. The weight of the generator will be taken through cast-iron supporting harrels through the turbine to the foundation below. The main units will be of the single-runner, vertical-shaft type, and will be installed in wheel chambers of spiral shape formed in the concrete foundations of the power house. The exciters will be of the same type, but smaller in size. The runners for these wheels will be an enlargement of a model runner, which, under test at Holyoke, gave an efficiency of 90 per cent.

About 100,000 yds. of concrete work and 2,000,000 yds. of rock and earth excavating will be necessary. It is expected that the plant will be finished in October, 1914.

INTERNATIONAL CONGRESS OF MINING.

One of the largest of the great scientific and industrial congresses is to be held in London in the early part of June, 1915. This is the sixth international congress of mining, metallurgy, applied mechanics, and practical geology. These congresses take place at intervals of five years, and the last, which was brilliantly successful, was held at Düsseldorf in 1910, previous congresses having been held in Paris and Liége. The attendance at the Düsseldorf congress was more than 2,000, and it is anticipated that the attendance in London in 1915 will be equally large.

FUEL FOR HEAVY-OIL ENGINES.

A BULLETIN recently issued by the U.S. Bureau of Mines consists of a paper dealing with heavy oil as a fuel for internal-combustion engines. The writer, Mr. Irving C. Allen, enlarges upon the varieties of liquid fuels, viz., gas oil, coal tar and tar oils, lignite tars, wood tars, seep oils and animal oils, and also upon the use of alcohols. The heavy-oil engine, its advantages over the steam and explosion engine for marine use, its maintenance cost and fuel consumption are fully described, and the various uses to which this type of engine may be satisfactorily consigned are enumerated. An important part of the subject, specifications for fuels and lubricants, is also exhaustively dealt with.

Concerning the desirable properties of fuel for the heavy-oil engine the writer has this to say:—

In selecting a fuel for this engine its composition as affecting combustion is most important. For proper combustion the fuel should be mobile and volatile, clean, and free from water, solid particles, and grit. In general the specific gravity of an oil rises directly as the vapor density. The boiling point and the amount of air necessary for combustion vary inversely with the volatility, and the greater the volatility of the fuel the better the ignition and combustion. The benzene-ring bodies, or benzol, seem to be more difficult to break up than the paraffin-chain bodies, and the latter have a better diffusibility than the former. They are, therefore, more active and seem to give better results in combustion, though for this same reason they are more dangerous. The calorific value of biuminous tars in general is lower than that of lignite tars or petroleum products. Petroleum benzines require approximately 40 volumes of air, whereas the heavy petroleum products require approximately 100 volumes of air for complete combustion.

Petroleum, gas oils, and lignite tar oils readily lend themselves to gasification and they leave practically no residue, giving them peculiar value in an oil engine. Anthracene and creosote oils gasify fairly well. Paraffin-chain bodies, in general, gasify very readily and are suitable for heavy-oil engines. Benzene-ring bodies, however, volatilize more difficultly. They volatilize regularly and do not have the explosive tendency to be noted in the several kinds of petroleum products, which gives the latter the value peculiar to oil engines. An oil, to give best results in a heavy-oil engine, should on heating show a tendency to volatilize suddenly at some given temperature and not to give off vapors regularly and uniformly, that is, distil with the rise in temperature. To this tendency to sudden volatilization or explosion, in contradistinction to regular volatilization or uniform distillation, is due the value as a fuel in the heavy-oil engine (unlike the explosion engine fitted with carburetor and igniter where the time of combustion is so short).

Lignite tar oils and bituminous tar oils mixed with 25 per cent. anthracene give good results in a heavy-oil engine. In general, in a good paraffin oil, the ratio of hydrogen to carbon, as shown by analysis, should be 10 to 15, and in bituminous tar oils the ratio should be about 10 to 12.5.

If an oil be heavy, with a very low content of "flashy" constituents, it should be enlivened by having mixed with it before admission into the cylinder about 2 per cent. of gaseous oil, such as the "gas oil" previously mentioned.

One gram of gasoline of specific gravity 0.71 to 0.73 requires approximately 15 grams of air for theoretically complete combustion, and under working conditions from 19 to 23 grams, whereas 1 gram of denatured ethyl alcohol, 90 per cent., requires theoretically 8 grams, and under working conditions from 9.5 grams to 11.5 grams. That is, under normal working conditions denatured alcohol requires about half the weight of air that gasoline requires; 25 to 50 per cent. excess of air, however, is necessary in both cases for best results; or, stated in heat units, denatured alcohol, 94 per cent. by volume, develops 5,833 calories per gram, whereas gasoline of specific gravity 0.71 to 0.73 develops 10,611 calories. Therefore the power developed by denatured alcohol and by gasoline is approximately 10 to 18 in favor of the gasoline. The difference in ignition temperature, a matter of prime importance in the Diesel engine, is also greatly in favor of the gasoline, because an explosive mixture of alcohol vapor and air can be compressed to over twice as high a pressure (180 pounds per square inch) as can an explosive mixture of gasoline vapor and air (70 pounds per square inch) before self-ignition takes place. Although explosion engines are hard to start with alcohol and are uncertain with variable loads, an explosion engine properly designed and regulated will run as well with alcohol as with gasoline; but less cooling water is required for the engine cylinders with alcohol than with gasoline.

Use of Water in the Cylinder.—It is believed that an auxiliary nozzle could be advantageously used to inject a small quantity of water into the combustion cylinder simultaneously with the fuel. The nozzle must be removed as far as practicable from the fuel nozzle, however, so as not to dampen the ignition of the oil by the steam thereby generated. During ordinary running the cylinders are continuously superheated and must be cooled by water circulating externally. This circulating water cools the cylinder; carries away considerable heat, and thereby causes a direct loss of fuel value. The water injected will generate steam or power by absorbing a portion of the surcharge of heat and converting it into power, and will at the same time reduce, at least in part the necessity for externally cooling the cylinders and thereby losing some heat. This principle has been practically developed by James Hargreaves in his internal-combustion engines, and might be applied, so far as practicable, to eliminating the explosion pound of internal-combustion engines in general. That an engine so fed with water will run more quietly and smoothly has been demonstrated by Strong in his gasoline-alcohol tests. Even as low as 50 per cent. alcohol and water has been burned by him in an explosion engine.

Relative Calorific Values of Some Fuels.—The calorific values of the chemically pure fundamental bodies found in liquid fuels is given below for the purposes of comparison:—

Heat of Combustion of Pure Liquids.

Substance	Specific gravity	Average Calories per gram
	0°.C	
Methyl (wood) alcohol, CH_3OH....liquid....	0.810	5,314
Ethyl (wine) alcohol, C_2H_5OH.....liquid....	.791	7,107
Hexane (paraffin), C_6H_{14}..... ..liquid....	.677	11,603
Benzene, C_6H_6 .....liquid....	.899	10,001
	15°.C	
Commercial gasoline	.710-.730	11,368
Commercial kerosene	790-.800	11,050
Crude California asphaltic petroleums:		
Coalinga (average of 53 samples)	.9462	10,501
Coalinga (average of 62 samples)	.9498	10,404
McKittrick (average of 26 samples)	.9566	10,282
Midway (average of 29 samples).....	.9570	10,341
Kern (average of 40 samples)	.9645	10,307
Sunset (average of 25 samples)	.9701	10,266
Average of asphaltic petroleums	.9574	10,350

MUNICIPAL CONTROL OF WATERFRONT.

By J. A. Oliver,
Mayor, City of Port Arthur, Ont.

MAYOR Oliver's address to the Union of Canadian Municipalities, in convention at Saskatoon, Sask., recently, strongly endorsed citizen control of waterfront. The gist of his paper is aptly summed up in his closing recommendations, in which he is quoted as advising thus:—

"Let no individual or corporation get between you and the water privileges if you can avoid it. Hold fast to every inch of waterfront you have. Acquire the balance by any reasonable means in your power. Control your waterfront and, if necessary, operate it, tolerating nothing that is a restraint on your trade and advancement; your sanitary requirements, and your pure air and water needs, and by all means endeavor to place something on the statutes to prevent towns to be established in the future from having to make the same up-hill fights that the majority of our cities on the waterfront are now facing."

From his paper the following potent remarks and suggestions are extracted:—

Possibly no other problem has confronted municipal representatives with as many difficult and serious problems involved, or no question is more vital to a city's interest and at the same time more hemmed in with almost unsurmountable difficulties as that concerning ownership or control of its waterlots. All agree that from every standpoint it is beneficial to every city to have complete and untrammelled control of its waterfront. Considered in the light of aesthetic, industrial and sanitary conditions, there should be no opposition to civic control. Instead of this, however, we find the waterfront of almost every city and town in a totally unpresentable condition, the derelicts of commerce stranded on the beach, and sewers drained into the water. Docks, elevators, warehouses and boathouses are placed in positions beneficial only to the owners, while railways own the whole or the greater portion of the waterfront, which ultimately becomes a network of tracks and spurs. To aggravate the trouble, many streets are closed, and traffic is thus thrown on a few, conditions then becoming dangerous. This all goes to show that in the strenuous rush for individual and corporation gain, natural beauty, scenic grandeur, landscape planning, sanitation, pure air and breathing spots have all been ruthlessly swept aside. At the same time, opportunities for civic commerce are restricted, municipal authority ignored, and the public, whose birthright has become the possession of the transportation corporations, struggle very ineffectively to win back the vital right of free entry.

It seems a wrong principle that as soon as a town site is laid out and plans adopted, the owner of land facing the shore can apply to government and receive deeds for the water lots in front thereof. The writer would suggest, therefore, that legislation be enacted to govern all new town sites, villages, etc., hereafter established making it imperative that the government grant the municipality the said water lots under a condition that the title can never be transferred by the city to any individual or corporation. The legislation should also allow cities to expropriate and hold water lots already deeded subject to similar conditions. By doing so, the city can advance trade and assist industries leasing sites carefully selected so as not to interfere with any civic plan, at a good rental with a reasonable increase from time to time.

It should be further suggested that a stated case should be taken to the Dominion Railway Board and a ruling obtained to the effect that no individual or corporation can prevent any person from gaining access to the waterfront or withhold trackage or spurs where asked for when the petitioners are willing to pay for any land necessary; because a persistent refusal is a restraint on trade and injurious to the general welfare of Canada.

Further, where conditions have already become acute, it would be advisable to take all ways and means to have the railroads themselves operate their railways and trackage within your city limits as a terminal railway, thus avoiding the necessity of duplicate and triplicate spurs and tracks, or the running of more than one company's cars and engines on one spur; the latter procedure being almost tabooed by railways to-day. Still better, however, would it be for the city to own and operate her own terminal railway as a municipal franchise. In the young city this would, of course, be difficult and expensive, but the municipality would be better saddled with a debt for a few years than to be cursed with the present load of trouble forever.

A municipal terminal would have to be managed by a commission, and the said commission could have, in addition, all the authority of a harbor commission. A harbor commission, such as now exists in Montreal, cannot be too strongly commended, uniting as it does assistance to trade and commerce, with sanitary cleanliness and the retaining of natural scenic and landscape beauties.

EXPERIMENTS WITH ROAD BINDERS.

Asphalt and asphaltic oils as binders are being extensively experimented with in the United States, while the use of tar has been adopted as standard practice in England and Scotland. It is essential to success with tar that it should be of uniform quality, and should be refined by heating to drive off volatile oils. Creosote and pitch are often added. The Ottawa Improvement Commission report that the use of a grade of refined tar has been attended with success. Other special materials which may be mentioned are glutrin, which is a bye-product in the manufacture of wood-pulp, and is used for spraying. An emulsified asphaltic oil is used, and another, a liquid compound, when mixed with powdered limestone, produces silicate of lime on exposure to the atmosphere. All these materials are as yet in the experimental stage, but up-to-date and progressive road authorities will not be averse to experimenting with promising materials, for only by practical tests can they discover the kind of road which is specially suited to their local requirements.

FRENCH ROADS.

An appropriation of $6,800,000 is being allowed this year for the upkeep of the 38,337 kilometres of national highway existing in France. This will represent an increase of $400,000 compared with a year ago, and will be an allowance of $243.6 per mile per annum for maintenance only. For 1914 it is proposed to grant the sum of $7,200,000 for the national highways, this being at the rate of $302.25 per mile per annum. These figures deal only with the national highways of France, which have a total length of 23,831 miles, and are entirely under the control of the central government. The three other classes of roads, which are more or less under local control, have a mileage of 339,867, giving a total for all classes of made roads in France of 363,698 miles.

THE CANADIAN PACIFIC RAILWAY BRIDGE OVER THE ST. LAWRENCE RIVER AT LACHINE.

By W. P. Murray, B.A.Sc.,
With Dominion Bridge Company, Erection Department.

THE erection of the 408-foot through channel spans of the Canadian Pacific Railway St. Lawrence River Bridge at Lachine gave rise to many interesting problems. The excessive height of approximately 70 feet clear of the water, a river depth of about 30 feet and a current of approximately 8 miles per hour were factors that had specially to be provided for in launching the spans.

The arrangement of the through and adjoining deck spans of the bridge was well suited to the end launching scheme. (See Fig. 1.) The 408-foot through span was assembled on camber blocking on the deck of the 269-foot adjacent span, so that three panels of the through span overhung the river. The camber blocking was placed over the panel points of the lower deck span, the chord of the through span being much deeper and stronger against bending than that of the deck span.

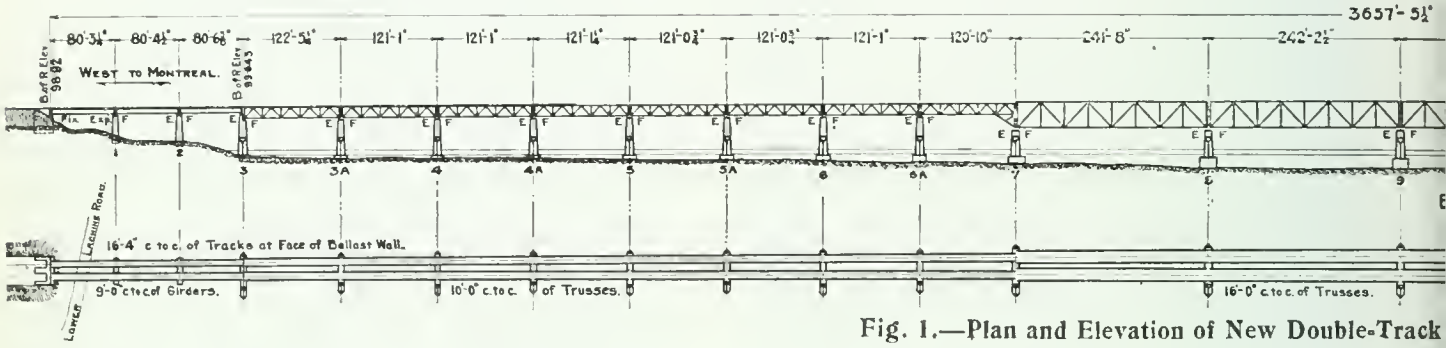


Fig. 1.—Plan and Elevation of New Double-Track

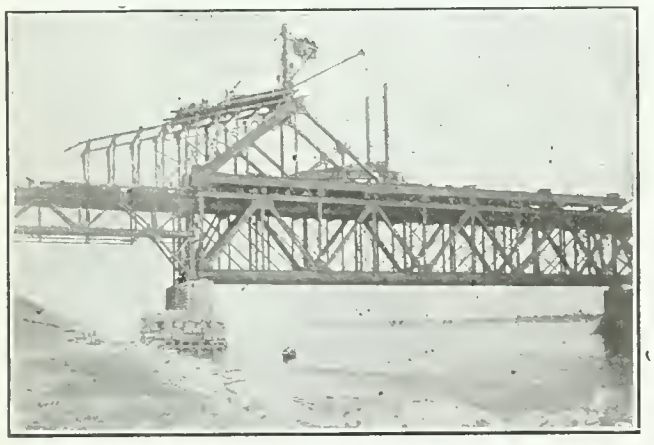

Fig. 2.—Showing Traveller on Falsework, and Camber Blocking.

The bottom chords and floor system, out as far as the end of the deck span, were placed by two derrick cars from the old track. The top chord type of traveller was used for assembling the remainder of the span, as Figs. 2, 3 and 4 show. This traveller was erected on an inclined track on timber falsework and pulled up to position for placing the members of the end panel, and then moved from panel to panel, adjustment being provided to keep the mast vertical at all times. A long and a short boom were convenient in handling the heavy chord sections. Steam was supplied to the engines from a boiler below the floor of the old span, through a flexible pipe connected to the engine on the traveller.

In assembling the overhanging panels, temporary bars were used to support the lower chord and post until the top chord was connected.

Specially dressed 10 by 10-inch hard pine blocking was provided at the end of the deck span to carry the excessive load due to the overhang of the longer span above.

The total weight of the span as launched was 1,300 tons, 900 tons being carried on the barge and 400 tons on the deck span during launching.

The floor system of the deck span being inadequate, to carry a concentrated load of 400 tons, necessitated the construction of a special carriage distributing the load over three points on a 40-foot base. The carriage had three pairs of shoes with a planed and polished plate on the bottom, which slid on a greased track of eight 100-lb. standard rails, placed directly over the stringers of the deck span. This arrangement is illustrated in Fig. 4. The centre pair of shoes were constructed to take the full load of 400 tons, which resulted when the forward pair of shoes slipped over the end of the deck span, throwing three-point distribution of the carriage out of commission. The end panel of the deck span was designed specially heavy to carry the concentrated load.

The barge was 200 ft. long by 37 ft. 6 in. wide, built of longitudinal steel trusses, steel brace frames and timber covering. Two 100-foot plate girder spans, borrowed from another contract, were used as a base to distribute the load on the barge. On top of the girders a tower of timber was constructed, composed of twenty-four 14-inch by 14-inch timbers for verticals strongly braced with steel cross frames and timber.

Water was admitted to the barge through four valves in the sides of the barge near the bottom until the top was clear of the span and placed in position beneath the span with 1-inch wire guys. Then sufficient water was pumped out to bring approximately one-half the load on the barge, the span being supported in this manner until ready for the actual floating operation.

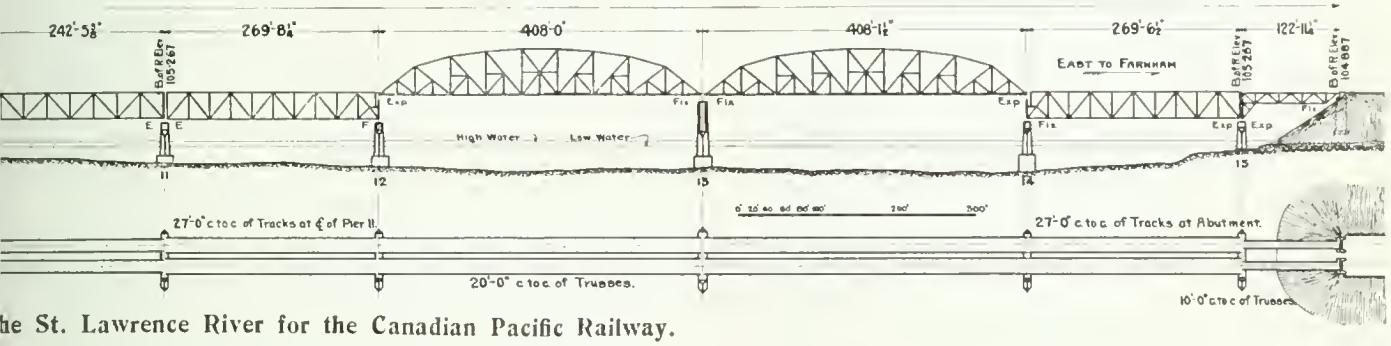
Two anchors were used to hold the launching barge in the swift current of the river, one, 1,400 feet upstream from pier 13, consisted of fifteen 5-ton concrete blocks threaded on a 1½-inch wire cable; the second consisted

of a 12-inch beam grouted in the rock on shore upstream from pier 14. From each of these anchors 1,000 feet of 1½-inch wire cable passed on to a light barge, which in

Fig. 3.—Span During Launching, Showing Hauling Apparatus.

turn was connected to the main barge by a 400-foot line of 1½-inch cable, operated by a steam hoisting engine.

The hauling apparatus for the actual launching of the span consisted of a 60-ton Lidgerwood ballast unloader,



he St. Lawrence River for the Canadian Pacific Railway.

anchored securely at the end of the skidding track, pulling on a two-part purchase of 1½-inch Samson brand wire cable. Fig. 3 illustrates the method. Steam was supplied by a C.P.R. locomotive.

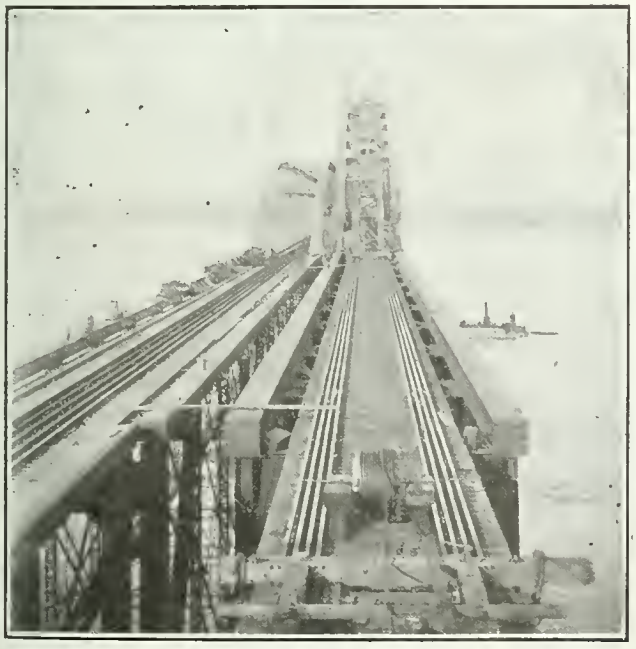


Fig. 4.—End View, Showing Old and New Spans. Also Skidding Track After Launching.

Although all parts of the anchorage and falsework had been designed for a 10 pds. per sq. ft. wind, acting on the total surface of the span, it was thought advisable to choose a day with little or no wind on which to perform the actual launching operation.

November 4th, 1912, being favorable, at 7 a.m. the pumps were put in operation. By 8.30 the south span on the downstream track was afloat and all blocking cleared away. The actual time of moving was about 30 minutes, but owing to stops, about three hours were occupied in launching the span on blocking on pier 13. On November 24th a similarly successful operation was performed in launching the second span, the north channel span of the downstream track, this operation completing the erection of the steelwork for the downstream track of the new bridge. The two 408-foot through spans and adjoining deck spans for the upstream track will be erected during the present year.

The steelwork was fabricated and erected by the Dominion Bridge Company, Limited, for the Canadian Pacific Railway, of which Mr. P. B. Motley is engineer of bridges. The details of the erection were planned and executed under the direction of Mr. Jas. Finley, general superintendent, and Mr. F. P. Shearwood, assistant chief engineer, for the Dominion Bridge Company.

Some interesting experiments have been carried out in Glasgow with the Ostermann system of "metalizing" all kinds of materials. The plant was installed in the works of Messrs. Stewarts and Lloyds, and during the experiments a considerable number and variety of articles in metal, glass, paper, wood, and stone were coated with metal so that when the articles were bent or hammered the coating showed no signs of bursting or peeling. Zinc, lead, tin, aluminum, copper, bronze, nickel, or alloys of any of them are forced in an atomized condition from the nozzle of the machine employed upon the surface under treatment. It is claimed for the system that it can be applied to many purposes for which galvanizing is unsuitable, especially to the coating of ships' bottoms and other large steel structures, that it can be used also for coating very light materials, such as the woven fabrics of aeroplanes or airships, and that it affords a guarantee against corrosion. Although new in this country, the system, it is said, has found considerable favor in Germany, where a large number of installations have been ordered by the Government for use in warship work.

The League of American Municipalities will hold an annual Convention in Winnipeg on August 7th, 8th and 9th. Among Canadians who will present addresses are T. R. Deacon, mayor of Winnipeg; H. H. Ruttan, city engineer; R. D. Willson, assistant city engineer, and Sanford Evans, ex-mayor.

REINFORCED CONCRETE IN MINES.

By F. M. Dixon, M.E.

CONCRETE is eminently suited for structural work in mines, according to a paper read by Professor F. M. Dixon before a meeting of the Institute of Mining Engineers of Great Britain, in June last, and the discussion which followed its presentation. Many points arose which indicate that its uninflammability, indestructibility through rot, oxidization, etc., make it material which seemed to be especially designed for mining purposes, and vastly superior to wood construction.

Four totally different classes of structural work are within the scope of the mining engineer. The writer dwelt upon the suitability of concrete, its advantages and its limitations respecting each as follows:

Surface Works.—It is now admitted that reinforced concrete will always be an admirable material of construction in these cases, though, of course, economical considerations may often decide that other materials have to be used instead. If settlement is likely to require providing for, reinforced concrete is the only satisfactory material. A few years ago a building erected at Tunis tilted over, owing to the failure of the foundations, till it was inclined at 25 deg. to the vertical. By excavating under the higher side and loading the building it was brought to a level bearing, and though now it is several feet lower than originally designed it remains an example of the bad treatment reinforced concrete may receive without failing. Its capability for resisting shock is also shown in its use for sleepers, piles, and various railway structures.

Shafts.—While plain concrete would in some cases be a very suitable material for use in lining shafts owing to its great crushing strength and to the ease with which it may be put in position, it is often quite impossible to use it in a satisfactory way. A considerable time is required for concrete to develop a reasonable strength, and therefore it is necessary that the expensive timbering or steel centres which support the green concrete should remain in place till this strength is attained. But it is quite feasible to use reinforced concrete in a way exactly similar to that in which a cast-iron curb is used. Reinforced concrete seems a suitable material for making a shaft lining by building it in cylindrical sections keyed and grouted together, the cylindrical sections being formed either by keying together several curved plates of reinforced concrete or by being cast in complete rings. Cylindrical tubes 7 ft. in diameter have recently been successfully made in this material and then lowered into trenches to form a main sewer.

Permanent Roads.—For these works reinforced concrete is the best material. Its great strength, resistence to shock and the effects of settlement and fire, and its durability, combine to make it superior to any other. When properly designed it will be found economical. Already it is used in several important mines in the country. In some cases it has been described as too expensive. Some engineers, however, use reinforced concrete like plain concrete; that is, the steel work is put in merely to ornament the drawings and make them appear up-to-date, there being ample concrete in place to carry all the load, and so naturally the method of construction appears costly.

Professor Dixon exhibited an experimental arch reinforced on the Monic system. This method of reinforcement, he explained, consists of embedding in the concrete a net of steel wires about 3 in. centre to centre, the diameter of the wires in the arch in question being about 0.34 in. The dimensions of the arch shown were 32.8 ft. span, the width being 13 ft., and the depth at crown 6 in. The following test loads were applied: First a locomotive weighing 40 tons was run across the arch. Then a locomotive weighing 53 tons was placed on the half span. Having stood these loads satisfactorily, a dead load of 110 tons was piled on the half-span. The deflection under this load was only 0.12 in. When the load was increased to about double this figure the arch failed owing to the abutments giving way.

Recently, at the University of Birmingham, some experiments have been carried out on the strength of arches on a reasonable though smaller scale than that of the above experiment. Arches 10 ft. span and 1 ft. rise are constructed, the width being 3 ft. A uniform load is applied by means of a pump and hydraulic jacks. Several arches in brick concrete and reinforced concrete have already been tested, showing failure at crown. The great strength of concrete and reinforced concrete arches was fully demonstrated. The depth at the crown of the concrete arches was 6 in., and the reinforced-concrete arch tapered from 6 in. at the springing to 3 in. at the crown. The total uniformly distributed loads supported by these arches when tested three months after making were 53 tons and 42 tons for the concrete and reinforced-concrete arches respectively, this giving crushing loads of 4,000 lbs. and 3,200 lbs. per sq. ft. of arch. It is hoped to carry out exactly similar tests on timber beams, but if a maximum fibre stress for a round 10-in. diameter beam of larch be assumed to be 4,000 lbs. for average conditions, then the breaking load of a solid floor of these 10-in. bars on a 10-ft. span would be about 2,500 lbs. per sq. ft.

It is evident from these experiments that there should be no difficulty in designing a light section in reinforced concrete with side walls and invert which might be depended on to support a main road in any ground. This has been done at several mines in England.

Temporary Roads.—It is in temporary roads, however, and as a substitute for ordinary timbering that an extended use of reinforced concrete in mines is suggested. In a paper before the Concrete Institute this year, the writer gave results of a number of experiments on reinforced-concrete beams and posts 8 ft. long. Such work is coming into use in the United States and Canada. In this method posts and beams suitably reinforced are made and stored ready for use. In many metal mines the broken stone, which makes admirable material for the greater bulk of the concrete, is being constantly mined, and so the sand and cement only needs to be brought into the mines, the beams and props being made and stored below ground. For use in mines the beams should be reinforced on the upper side as well as the lower to save accidents in transport. For posts the reinforcement should be of the simplest kind, the object aimed at being chiefly to render the posts portable and secure against shock. It would be easy to suggest other shapes than round or square as being probably more economical in mines. For example, it may be shown that a triangular shape might be best for both beams and props, and a series of experiments carried out on a simple triangular section gave excellent results. Also the ends of posts and beams might be modified for the sake of getting better bearings and also for increasing their strength. The successful economical manufacture of the structures will

depend to a very large extent on the design of the forms and moulds, and there is no doubt that in a short time it will be possible to order these small structures for delivery just like timber or steel.

The advantages of these posts and beams when used will be obvious. Besides their considerable strength, the following points may be noticed: They will be durable. It has been proved conclusively that a steel prop, if embedded in concrete, is not deteriorated by time under the most severe conditions. The strength increases with age to a maximum and then does not decrease. The strength is not to any great extent affected by moisture, the material in this respect differing much from timber. It may be roughly stated that timber when wet has only 50 or 60 per cent. of the strength which it would have when dry, and, as is well-known, in a dry heading the timber rots quickly. All tests (outside mines it is true) show that of all materials of construction properly constructed reinforced concrete is the best for resisting destruction by fire.

A further advantage that the use of these posts and beams presents is that the method of erection, while being as rapid as the ordinary method of timbering, could be at slight expense converted to permanent construction. This would be done by fitting reinforced slabs between the settings or by ramming plain concrete between them. Modifications of design would always allow this to be done.

AIR AND WATER PURIFICATION BY OZONE.

THE commercial and hygienic value of the powerful oxidizing activities of ozone in the matter of attacking and destroying organic impurities was recognized in Europe at a somewhat earlier period than in this country. There it was first applied on a large scale to the sterilization of water supplies, and later to the purification of air. These applications have produced such satisfactory results that the question of the practicability and effectiveness of sterilization, by means of ozone, has passed beyond the stage of discussion. In fact, the many advantages of the method are so obvious, particularly its low cost, certainty of operation, simplicity, uniformity of results, and above all, absence of poisonous residue or taste, that it is likely to be universally employed where the sterilizing of water on a large scale is a necessity.

The principal existing installations of this class are the large municipal plants at St. Petersburg, Paris, Chemnitz, Nice, Madrid, Milan, and Paberhorn. Extensive plants are also in operation in many other places. Several of these installations were described in an article appearing in July 10th issue of *The Canadian Engineer*. That the method is entirely satisfactory is demonstrated by the decision of the Duma of the city of St. Petersburg to greatly increase the capacity of the existing plant at a cost of $5,250,000.

It is noteworthy, however, that although Europe is ahead of us in the application of ozone for sterilizing water, this continent leads in the development of small ozonator devices for purifying the air. This is due to the fact that in general the attitude of European engineers tends to limit the use of small apparatus, it being their usual practice to recommend highly developed systems, where the application of the method is either necessary or desirable. The practice here commenced with portable machines, and consequently considerable ingenuity has been displayed by the Canadian General Electric Co. in the design of small household types of apparatus which serve greatly to extend the field of application.

Of the European systems designed for the specific purpose of purifying the air, the general application of ozone to the subways of London is most extensive. In this case 8,000,000 cubic feet of air per day are ozonized, and conditions which previous to the installation were subjected to much adverse criticism, are now most favorably commented upon by the patrons of the underground service. Another notable installation is that of the Central Refrigerating plant, at Hamburg, affording storage for upwards of 14,000,000 barrels of salted herring. This is an example of the application of ozone for the purpose of destroying all odors, the operation of the installation being highly effective in rendering entirely inoffensive odors emanating from the stored herring. Another interesting installation is that on board the German trans-Atlantic steamship "Imperator." This vessel, the largest afloat, is equipped with a complete system of ozone-producing apparatus for the purpose of aiding ventilation, destroying odors, preserving food stuffs, purifying water, etc.

In Europe, many of the abattoirs are provided with ozonizing apparatus which completely destroy the odor common to such establishments, thus rendering them entirely unobjectionable to neighboring residents. This is particularly noticeable in Germany, where the application of highly developed methods of employing ozone, for purifying and deodorizing the air within and around industrial plants located in urban districts, is becoming very common.

The production of ozone for such purposes can be undertaken with a high degree of efficiency and on a basis of economy which permits and warrants its application in many fields already developed and in speculative fields which are almost limitless.

STONE OR CLAY HANDLING.

Cars which are to be used in quarry service for carrying the stone from the quarry to the crusher should meet the following requirments:—

First—Height from ground to top of bed should be as low as possible, paricularly if cars are to be loaded by hand.

Second—Cars should be able to be dumped instantaneously and automatically when they arrive at crusher, both to save time in unloading and to save the cost of unloading by hand.

A large number of different designs have been made up for such service, but it is not possible to make a car, the body of which will dump without also making it so high that it cannot be loaded by hand, if the capacity of the car is to be large enough to make it economical. This, of course, does not apply to cars which are loaded by a steam shovel, as the height of these cars can be several times as high as the car which is to be loaded by hand, but a low car is also an advantage for steam shovel service, as it makes it possible for the steam shovel to load the cars for a longer time without shifting the tracks. There have been several designs of cars made which had a separate body hinged on one side to the underframe, in connection with which an air or electric hoist engaged a side of the car opposite crusher, lifting the body up so that the load would slide into the crusher. A car constructed in this manner, however, is very expensive, as it requires practically two underframes, and if a large number of cars are used, the cost of the equipment is increased excessively.

ASPHALTIC CONCRETE AS A PAVING MATERIAL

CONSIDERED SPECIALLY WITH RESPECT TO RESIDENCE STREETS, SUBURBAN DISTRICTS AND BOULEVARDS—VARIETIES OF ASPHALTS USED—THEIR QUALITIES AND SIMILARITIES.

By LINN WHITE,
Chief Engineer, South Park Commissioners, Chicago.

IN his paper to the Civil Engineers' Society of St. Paul, and appearing recently in the Journal of the Association of Engineering Societies for June, Mr. Linn White refers to the most suitable pavement as one requiring the study of such influences as the kind of traffic which it is to bear, character of district served, probable future growth, limitations as to cost, nature of soil and climatic conditions, provision for maintenance, etc. The streets of a heavily travelled business district require, first of all, a permanent surface on an unyielding foundation, and the question of cost properly receives but secondary consideration. It is regrettably true, too, that the important considerations of cleanliness and noise generally receive only secondary or later consideration.

On light traffic streets, or those of mixed service, permanency is hardly so imperative, and the consideration of cost becomes more important. Here, also, the future growth or probable change from a district partly occupied by residences to one devoted entirely to business should receive careful consideration.

A third general class of streets, comprising residence streets, boulevards and those serving suburban districts, is the class it is proposed to discuss in this paper. The general character of the districts served may be considered fairly well established, so no great changes in *kind* of traffic may be anticipated. The traffic on such streets is seldom what is probably termed "heavy," but may be "intense," that is, there may be a great many rapidly moving, comparatively light vehicles. Automobiles will predominate, with a lesser number of horse-drawn passenger vehicles. At times, heavy teaming of building material, produce, coal, etc., must be provided for, and the general delivery and express service for the district.

To satisfy the requirements of such cases, a pavement must have many high qualities, and the standard is all the time growing higher, the public exacting and expecting better service. It must be reasonably permanent, moderate and flexible in cost, serviceable on all kinds of foundations, sanitary, smooth, dustless, noiseless, non-slippery, resilient, and agreeable to the eye in strong sunlight. Quite a formidable list of virtues difficult to attain.

Examining the different generally known kinds of pavements we will at once pass up many of them as possessing in an eminent degree only a few of the qualities named. Brick, concrete, stone block and wood block all possess some of these qualities but are lacking in others. Macadam cannot be classed as a permanent pavement, and we are thus reduced to some form of bituminous paving surface.

Sheet asphalt (sand asphalt) pavement is the best known and most widely used form of bituminous pavement—at least, it has been so for years past, though now other forms are becoming extensively known. Sheet asphalt must, however, be made comparatively thick, say, three inches, to conform to accepted standards; its cost is comparatively high, dependent on its thickness, though not in direct ratio thereto; it is suitable for use only on a concrete base; has a smooth, sheet-like surface more or less slippery; and last but not least has fallen somewhat into disrepute because of the skill and care required to produce a successful paving mixture and the constant effort during recent years to reduce its cost.

Asphalt block is a pavement that has been in existence for many years, but has not come into general use because of its high cost and difficulty of manufacture and transportation.

Macadam surfaces bonded by the application of bitumen in a liquid form have come largely into use during recent years, but have not established themselves as a standard type of pavement because lacking in the very essential quality of permanency under considerable traffic. Their place is on the country highway and roads of occasional traffic.

Having thus briefly reviewed the principal varieties of street pavement known and used in this country, we come to the one remaining general variety, designated as "bituminous concrete." Under this general name is included all paving mixtures consisting of broken stone combined with sand or other fine mineral matter, cemented together by a bituminous binder, which may be either tar or asphalt, making either "tar concrete" or "asphaltic concrete."

While both tar and asphalt are hydrocarbon compounds, their qualities are quite different. Tar, for practical use in a pavement, cannot have a melting point much higher than 130 degrees Fahr., as it would become very hard and brittle in cold weather. In this climate it is not unusual to find temperatures of 115 or even 120 degrees Fahr. on the street surface, under which conditions a tar binder melting at less than 130 degrees would be almost liquid and have but little cementing or bonding value. In other words, tar, while quite adhesive and ductile, is very susceptible to changes of temperature. For these reasons it will not be considered further in this discussion.

The various asphalts that may be used in an asphaltic concrete have very different qualities and require different treatment, which will be briefly alluded to later.

For a paving mixture to merit the name of asphaltic concrete, the broken stone, according to a definition adopted by the American Society of Municipal Engineers, must be in sufficient quantity to form an important part of the mixture; also the ingredients must be combined and mixed before being laid. Neither the size of the stone nor the proportion of the various sizes in the mixture can be limited by the name "asphaltic concrete," any more than the size and proportions in a hydraulic concrete can be limited by the name. This can be done only by the specification of the particular mixture it is desired to produce.

Several varieties of asphaltic concrete are offered on the market under trade names, copyrighted or patented,

that presumably conceal or but half reveal their somewhat mysterious qualities, such as Bitulithic, Amiesite, Filbertine, Warrenite, Westrumite, etc. They are all asphaltic concretes founded on the old concrete idea of a broken stone aggregate supported and held together by a mortar matrix.

The first one named, Bitulithic, is supported by letters patent in which the principle of filling the voids in the aggregate by the use of successively smaller sizes down to impalpable powder is exploited. It is claimed by this method of grading the sizes of the mineral that an "inherent stability" is produced in the pavement independent of the asphaltic binder, which then may be very soft and serve only to waterproof the mixture and to fill the remaining small percentage of voids. Several patents have been issued to the originators of this pavement, the claims of which to the lay mind seem very similar, all of which rely upon this main idea of carefully grading the aggregate, and some of which describe carefully the process of separating the mineral into a number of sizes and recombining them according to a definite formula. This brings out the idea of "predetermining the sizes" of the mineral aggregate, which is a phrase met with in Bitulithic literature.

There is another claim in the Bitulithic patents that is an excellent one if carried out to its logical conclusion, that is, that by reason of filling voids so completely by grading the mineral the quantity of asphaltic binder may be reduced and the pavement "produced at a smaller cost." This is a quotation from the claims of the patent, and if *produced* at a smaller cost it naturally should be sold at a smaller cost, thus justifying protection under the patent laws and earning the gratitude of the nation.

These references are made to the claims of the Bitulithic pavement disregarding the other special asphaltic concrete pavements named above because the Bitulithic is the only one that endeavors so to broaden its claims as to monopolize the field of asphaltic concrete paving. If we sum up the claims of the Bitulithic patents, we find they hinge upon, and in fact are reiterations of, the principle of reducing voids by carefully graded sizes so that an "inherent stability" is produced and less bitumen used, thus reducing cost and increasing usefulness.

If it is true that Bitulithic methods are the best and cheapest, it becomes the duty of every engineer and city official to support them and use them. Let us examine the situation a little further and see what conclusions can be drawn on this point.

It cannot be contended that good Bitulithic pavements are not produced, for many excellent examples may be found throughout the country. At the same time, many excellent examples may be found of sheet asphalt pavements, and it cannot be contended there is any "inherent stability" in the sand of which they are composed. All the stability must be supplied by the asphaltic cement.

In 1907 a contract was let to the Bitulithic Company for about three miles of pavement on Michigan Avenue and South Park Avenue in Chicago, which was laid during 1907 and 1908. On these avenues there is but little heavy teaming, as they are boulevards and under usual boulevard restrictions as to traffic. In 1908 a traffic census showed from 3,000 to 5,000 vehicles per twenty-four hours on the three miles of pavement in question, which by 1912 had increased to from 5,000 to 12,000 per twenty-four hours—practically doubling the average number.

During the summer of 1909 some small portions of the surface began to show a tendency to form waves and ruts, but was scarcely noticed, being considered only local or accidental defects. It was not thought there could be anything very serious the matter; the spell of "inherent stability" was too strong. By the summer of 1910 conditions were much worse, and the contractors put heavy rollers on to smooth out the waves and ruts, also attempting to roll into the surface, first, limestone screenings, then granite chips, and, finally, crushed granite about three-quarters of an inch in size. These expedients one by one failed. The screenings, chips and crushed granite could not be forced very deeply into the surface and most of the particles were easily loosened and torn out again by the traffic. It was found that while the rollers smoothed out the surface it wouldn't stay smooth, but quickly formed ruts again as long as warm weather continued. By keeping the rollers going more or less all the time until cooler weather arrived, the streets were kept in fair condition for the winter, but early in the summer of 1911 the campaign had to be begun again.

This season it was prosecuted more vigorously. The crushed granite was coated with bitumen to make it bond more effectually into the body of the pavement.

The surface of the street was punctured full of small holes into which the coated stone was swept and then rolled. These efforts were all of doubtful and temporary value. Conditions all the time grew worse, and it is safe to estimate fully $20,000, or from 25 to 30 cents per square yard, was expended by the contractors during the three seasons named without materially improving the condition of the pavement.

In the summer of 1912, under strong pressure from the Park Board, they abandoned their efforts to stiffen up the pavement and resurfaced the whole area with a layer of new asphaltic concrete about 1½ in. thick. The method followed was to go over it with surface heaters, softening up the surface until about an inch in thickness could be removed with rakes. Then the new 1½-in. layer of asphaltic concrete was spread and rolled, thus making it about ½ in. thicker than formerly. After this resurfacing the pavement was left in excellent condition at the end of the season of 1912 and so remains up to the present time.

It is to be noted the original pavement was specified to be at least 2 in. thick and actually averaged 2½ in. throughout a large portion of it; also that the original binder was tar. Thus the pavement is now composed of 1 to 1½ in. of tar concrete, overlaid with 1½ in. of asphaltic concrete.

In extenuation of the troubles on this particular pavement it may be pointed out that there are many excellent examples of Bitulithic pavement to be found. This is true. There is one other piece of Bitulithic pavement in Chicago, about one-half mile long, on Sheridan Road, which is as fine a piece of pavement as can be found, and it is older than the Michigan Avenue pavement. But it is from one failure like this that we can learn more than from numerous successes that teach nothing.

It may also be argued that the traffic on Michigan Avenue was extremely severe, or that if the original binder had been asphalt instead of tar the result would have been better.

This may be true, but it is not to the point. The main point is the very important "inherent stability" was not in the pavement to resist displacement independent of

the support of the binder; and if it was there at all it was not sufficiently "inherent" to resist the severe traffic.

The traffic, while severe, was not prohibitive—was not sufficient to strain a good asphaltic concrete pavement beyond a safe limit. It was merely a severe test and developed a weakness that might have developed to a lesser degree or more slowly under lighter traffic.

In 1909 an asphaltic concrete pavement was laid on Michigan Avenue, between Twelfth Street and Jackson Street, which in 1911 was carrying a traffic of 17,000 vehicles during twenty-four hours. This was not laid by the Bitulithic Company nor under their specifications, and was the subject of a suit between the Bitulithic Company and the South Park Commissioners, of which more will be said later. No trouble has occurred with this pavement up to date except a comparatively small number of cracks which have in every case been traced to the concrete base. In explanation it should be said the street between these points is 75 and 85 ft. wide between curbs, having been widened 35 feet to the eastward when paved in 1909. Thus a portion of the sub-foundation is new filled ground and a portion the old street, and the support is uneven. Also the construction of a number of large buildings on the west side of the street has caused settlement in places and consequent cracks in the pavement.

This pavement is between the Bitulithic pavement and the centre of the city and carries a larger traffic.

There were also asphaltic concrete pavements laid adjoining the Bitulithic on Michigan Avenue at 39th Street, and on South Park Avenue at 35th Street. They are on both avenues extensions of the bitulithic to the southward and carry the same traffic in slightly decreasing numbers. No trouble has occurred with these pavements and they have cost nothing for repairs up to date except on two intersections where the cross traffic was quite severe and has occasioned minor repairs.

As stated above, neither Bitulithic methods nor formulas were followed. No special care was taken to grade the aggregate except to be sure there was plenty of mortar to fill voids and the fine material in the mortar was in proper proportions to give a well-filled mixture. Beyond this the success of the pavement depended on the proper preparation of the base and the use of a suitable asphaltic binder. Dependence was had on only common-sense methods to resist lateral displacement, and the paving mixture was intended to be waterproof for obvious reasons. The heating and mixing was done in portable plants working on the street; the proportioning of the mineral ingredients was by wheelbarrow loads; and the prepared material was delivered quickly and directly on the street surface. Much of the success and moderate cost were doubtless due to the methods and machinery used. There was no overheating or chilling of material due to long hauls, no separation of ingredients from the same cause, and no bad work on account of delays either at the plant or on the street. The concentration of all operations in one place, under one superintendent, undoubtedly tended to better results in many ways.

The comparison of cost between the three sections of pavement referred to above is as follows:

The bitulithic by contract cost $1.90 per sq. yd., exclusive of cost of base. Asphaltic concrete by contract on Michigan Avenue, between 12th and Jackson Streets, $1.73 per sq. yd., including concrete base, which would make it exclusive of base about $1.10 per sq. yd. Asphaltic concrete laid by day labor on Michigan Avenue, south of 39th Street, and on South Park Avenue, south of 35th Street, less than 75 cents per sq. yd., exclusive of base.

Following are the analyses of the mortar constituent (that is, 10-mesh material or less) of several samples of asphaltic concrete which have been under traffic for long enough periods of time to demonstrate their good or bad qualities. The first four proved to be very good, and the latter two indifferent in quality.

	No. 1 Jackson and La Salle	No. 2 Jackson and Main	No. 3 Michigan and Park	No. 4 Grand and Okwd	No. 5 Jackson and Franklin	No. 6 Jackson and Market
	%	%	%	%	%	%
Bitumen	18.8	18.9	16.1	21.0	18.9	16.3
200-mesh	10.8	11.6	11.7	10.9	4.3	3.5
80- "	10.6	11.5	7.0	26.2	5.9	5.7
40- "	36.8	35.3	22.7	19.3	50.3	54.1
10- "	23.0	22.7	42.5	22.6	20.6	20.4
	100.0	100.0	100.0	100.0	100.0	100.0

As far as the coarse aggregate is concerned, that is, all material coarser than 10-mesh, there were considerable variations in the different samples, but the total quantity was approximately the same, and the variations seemed to have nothing to do with the success or failure of the sample. Samples 1 to 4 were successful, and they were rich in dust and reasonably well proportioned in other sizes up to 10-mesh. Samples 5 and 6 were practically failures, and they are seen to be lean in dust with an excess of 40-mesh material not well filled by the smaller sizes.

Here is where stability is found, or such "inherent stability" as belongs to the mineral aggregate of asphaltic concrete, not in the careful grading of the larger sizes. It would not matter if there was 25 or 50 per cent. of mineral larger than that passing a 10-mesh screen added to the mortars of samples 1 to 5; the result would have been the same. Nor would it matter if this 25 or 50 per cent. of coarse mineral was all of one exact size or of several carefully graded sizes; the pavement would have been good. Therefore, in the making of good asphaltic concrete, it is an axiom that we must have a good mortar, well proportioned as to mineral, with a good asphaltic cement to bond it properly together. Having this, the coarse aggregate may be added with considerable freedom. There are, of course, certain precautions that must be taken and certain useful refinements that may be attained, as in the making of other bituminous pavements. For instance, too much dust in a mixture will require more asphalt, etc. All such points could not be covered in such a discussion as this, but the principles stated above may be taken as fundamental.

There are on the market two general classes of asphalt binders, or asphaltic cements, as they are more properly called when of a character suitable for use in paving mixtures, distinguished generally from each other by the presence or absence of any considerable degree of ductility. Ductility is the quality that enables a substance to be drawn out like chewing gum without breaking. It is of no direct value in the paving industry, but is supposed to indicate other qualities of value such as cohesion and adhesion. At the same time it indicates other objectionable qualities, such as susceptibility to changes of temperature. A considerable degree of ductility is required in most sheet asphalt specifications, but engineers conversant with the most successful practice in asphaltic concrete work agree ductility is not an essential quality.

It may be conservatively said that good work can be done with either ductile or non-ductile asphalt, with simplicity of manipulation somewhat in favor of the non-ductile material.

These statements, however, are not intended to dispose of the question of which is the most durable under heavy traffic or to suggest that one class be chosen in all cases to the exclusion of the other.

Successful foundations may be made of either concrete or macadam. Where traffic is comparatively heavy, unquestionably the concrete base has the advantage of greater rigidity, more "inherent stability." On the other hand, macadam in some cases may be the more advantageous to use. It does not have to stand so long to set up before you can apply the wearing surface, consequently the street is not out of service so long, and if you are working over an old street, where there is some old macadam in a more or less worn-out condition, frequently considerable economy can be effected by using a macadam base. This is a question for the engineer to work out in each case.

One principle may be laid down to apply to either concrete or macadam base. Don't finish it up smooth, but leave the surface rough and grainy, so the paving material may be forced into the interstices.

The specifications promulgated by the Association for standardizing Paving Specifications go into the question of preparing the base pretty well.

Some litigation was had in Chicago with the Bitulithic Company, of which the following is a brief statement:—

In 1909, when the South Park Commissioners let a contract for paving Michigan Avenue from 12th to Jackson Streets with asphaltic concrete, the Bitulithic Company sought an injunction in the federal circuit court. The injunction was denied by one judge, but under some legal technicality the case was reopened before another federal judge in the same circuit. Injunction was again denied, and as this left the case before the court in such a shape that any further action would have to be a trial on its merits, the complainants dismissed the complaint and no attempt has been made since to renew it. To reach this partial conclusion in the courts required over a year, and of course before then the contract over which the litigation started was completed and the pavement in use. The South Park Commissioners, however, had proceeded to lay other considerable quantities of similar pavement and if good grounds for an injunction had been shown the result would have been to force them to come to terms with the Bitulithic Company, and account for royalties on both past and future work.

Up to date, considerably over one million yards of asphaltic concrete pavement has been laid in Chicago and the royalties would amount to a considerable sum.

It is unfortunate the Chicago case could not have been fought to a conclusion on its merits, as this might have made it possible to secure a Supreme Court decision on the Bitulithic patents and determine just what of their claims are valid. Several other decisions have been rendered in litigation of this patent, which are more or less conflicting, some in their favor and others contrary. It has been the policy of the patentees not to push any case to a conclusion where the preliminary rounds have been against them. For this reason it has been impossible to get an appeal into the Supreme Court.

IMPULSE TURBINES OF NOTE.

The two largest impulse turbines built to date, each capable of producing 20,000 h.p., have recently been installed in the Pirahy plant of the Rio de Janeiro Light and Power Company in Brazil. The wheels operate at a speed of 300 revolutions per minute under a head of 900 feet. These two units are an addition to the Pirahy plant, where six 9,000 h.p. units have already been in operation, and will bring up its total capacity to 94,000 h.p.

A close second to this record is found in the White River plant of the Pacific Coast Power Company of Seattle. In this case, each turbine was designed to develop 18,000 h.p. at 360 revolutions per minute under a 440-foot head. However, in consideration of the lower head and the fact that these turbines can totally carry 20,800 h.p. they must undoubtedly be of greater bulk than the new units of the Rio de Janeiro Company's plant.

INCREASED DRAINAGE OF ONTARIO FARMS.

In the report of the Minister of Agriculture for the Province of Ontario, mention is made of the campaign which the Ontario Agricultural College is carrying on for the assistance and encouragement of farmers in the matter of drainage work. It is in charge of the Physics Department of the college, and is carried on in co-operation with district representatives, and the enterprise is very successful, as is shown by the accompanying table:—

Year.	Surveys.	Acres surveyed.	Miles of drain.
1906	15	500	45
1907	70	3,500	350
1908	100	5,000	510
1909	179	5,157	613
1910	383	14,672	1,800
1911	327	15,211	1,864
1912	293	17,212	2,278
Totals	1,367	61,252	7,460

GRAPHITE IN CEYLON.

The graphite of Ceylon being about half exported to the United States, a chapter is devoted to it in the last report on the mineral resources of the United States. The mineral is found over a fifth of the island, in the mountains of the south-west and west, but, instead of being disseminated through the gneisses and associated rocks, it occurs chiefly as veins along fracture planes, being, therefore, of later origin than the rocks. The veins are from an eighth of an inch to several feet wide, some not more than two or three inches being worked. The masses of graphite, usually pure, but sometimes mixed with pyrite and milky quartz, are aggregates of needle crystals; but in one mine a remarkable cavity or "rug," of oval section and about 15 feet high and a yard wide, was lined with flaky graphite, which completely filled the bottom of the cavity. The mines, usually less than 100 feet deep, sometimes go down 400 or 500 feet. Steam pumps and hoists are sometimes used, but very primitive methods are mostly employed. Directly or indirectly, 50,000 men, women and children are given work by the mines. The deposits are clearly not metamorphosed coal or asphalt, and the theories suggest that they came from some solution of metallic carbides, hydrocarbons, or other carbon compounds.

THE PRESERVATION OF IRON.

In a Carnegie memoir submitted to the Iron and Steel Institute by Dr. J. Newton Friend, some useful information is given as to the value of paint as a preservative for iron and steel.

His results reveal a number of interesting facts of considerable technical importance which may be enumerated as follows:—

(1) The surface of a paint film does not always give a correct idea of the extent of corrosion taking place beneath.

(2) The addition of small quantities of paraffin wax to paint destined for the protection of iron and steel exposed to the air reduces the corrosion very appreciably. If the paint is required to set at the normal rate, not more than 1 lb. of wax should be used for every 1,000 lbs. of oil present in the paint. If, however, the rate of setting is less important, the amount of paraffin wax may with advantage be increased to 3 lbs. per 1,000 lbs. of oil. This latter is, roughly speaking, equivalent to 2 lbs. of of wax per ton of ready mixed paint—an estimate that is sufficiently near for the purpose.

(3) In the case of plates immersed in water the addition of the paraffin wax seems rather to assist corrosion than to diminish it.

(4) A fine pigment is superior to a coarse one in the preparation of protective paints, a fact which is now generally recognized.

(5) It is generally believed that two coats of paint preserve an iron surface from corrosion considerably more efficiently than one coat. Liebreich and Spitzer have recently called attention to the fact that in their experiments, by increasing the number of coats of paint not only was the corrosion not reduced, but it actually increased, as if the extra coats stimulated corrosion. Dr. Friend's results lend support to the work of Liebreich and Spitzer.

(6) It is always found that a rusty surface when painted yields unsatisfactory results, and the careful painter removes the rust prior to the application of paint. Undoubtedly this is necessary in damp weather, and it is also necessary to scrape off any scale and thick coats of rust.

It occurred to the author, however, that a slight coating of rust, absolutely free from caking and lumps, might be an advantage rather than otherwise, if perfectly dry, for two reasons: (1) Fine rust is practically a pure ochre, very free, in the case of wrought iron and steel, from silica. Hence the surface is very absorbent, and if painted with a good coating of thin paint a similar result may be expected as by first laboriously cleaning the metal and then painting with a thicker paint—that is, one containing more pigment in proportion to oil than the former. (2) If the iron surface is sandpapered down it is made much smoother, and its area is reduced to a minimum. If, however, the rust is left on as a thin coating, the underlying surface of metal in contact with the rust is slightly pitted and uneven. Hence when the paint is applied it has a larger surface to grip, and its tenacity will therefore be increased in proportion.

It was found that plates suffered far less from corrosion when painted in a rusty condition than when first polished bright before painting. This is a remarkable result. It would seem, therefore, that when the painter is called upon to protect by painting thin sheets of iron, such as galvanized iron, which has already rusted somewhat, any lumps of scale should be removed, and a coat of paint applied in warm, dry weather to the rusty surface. The danger of the sheets rusting through will thus be considerably less than if the rust is first carefully scraped off and the metallic surface polished with sandpaper before the application of paint, as is the more usual custom.

UNITED STATES RAILWAY BUSINESS FOR MAY.

During May the railways of the United States received for their services to the public an average of $8,230,000 a day; it cost to run their trains and for other expenses of operation $5,920,000 a day; their taxes were $341,500 a day; their operating income $1,972,322 a day for the 220,897 miles of line reporting, or at the rate of $8.93 for each mile of line for each day. Thus for every six dollars of their earnings which remained available for rentals, interest on bonds, appropriations for betterments, improvements and new construction, and for dividends, the railways had to pay more than one dollar in taxes.

All of these amounts are substantially greater than the similar returns for May, 1912. They are from the summary of the earnings and expenses compiled by the Bureau of Railway Economics from the monthly reports of the steam railways of the United States to the Interstate Commerce Commission. They include over 95 per cent. of the mileage and earnings of all of the railways of the country.

PAVING BLOCK PRODUCTION.

The total production of paving brick and paving blocks in Canada in 1911, according to statistics contained in the annual report on mineral production in Canada by John McLeish, B.A., was reported as 5,220,400, valued at $79,444, as compared with a production of 4,215,000, valued at $78,980 in 1910.

This paving brick is made at West Toronto, Ont., from shale obtained from the banks of the Humber River. The annual production has for a number of years varied from 3,000,000 to over 5,000,000 per season, and the output finds a market chiefly in Toronto. Statistics of production are available since 1897; the average price per thousand has varied from $8 to $20.

The imports of paving brick have during the past three years exceeded the domestic production. During the calendar year 1911 the imports were 11,450 thousand, valued at $164,292, or $14.34 per thousand, and included 4,988 thousand, valued at $78,201, or $15.68 per thousand, from the United States, and 6,462 thousand, valued at $86,091, or $13.32 per thousand, from Great Britain. The imports during the calendar year 1910 were 10,503 thousand, valued at $124,994.

In the following table, compiled by *The Canadian Engineer*, are given the Canadian imports of iron, steel, etc., from Great Britain for June of this year and last, and for the first six months of each year:—

Item.	Tons in June. 1912.	1913.	Tons in first six months. 1912.	1913.
Pig iron	5,339	3,363	26,161	11,963
Wrought iron bars	484	1,074	2,928	4,724
Railway rails, etc. (iron and steel)	....	10	274	297
Steel bars, etc.	833	3,044	4,104	18,011
Tinned plates and sheets	249	452	3,778	4,320
Galvanized sheets (flat and corrugated)	2,367	2,519	10,711	18,475

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

LAKE OF THE WOODS WATER LEVEL.

A report is to be expected about October 1st from the International Joint Commission respecting water levels in Lake of the Woods. Different municipalities and companies have different opinions as to what these levels should be, based, undoubtedly, upon the bearing any changes will have upon their own interests. The dissension is common to both sides of the boundary, and it was, therefore, consigned to the Commission for decision.

Although not itself on the boundary, the town of Kenora, Ont., recognizes how vitally important the boundary water level is to its water power development. The Commission of Conservation places the available horse-power at a minimum of 4,100 for the east branch and 18,000 for the west branch of the Winnipeg River, based upon an 18-foot head; and of this amount some 6,300 horse-power is already developed. Naturally, the corporation's electric plant desires any change of water level to be a raise. The navigation interests also feel that the levels cannot be too high to suit them.

On the other hand, high water conditions interfere with fishing, and followers of this industry have protested lustily against any change, but one of lowering, in which contention they are upheld by the landowners, whose property, bordering the lakes and streams in the vicinity, is in danger from overflow. The interests at International Falls, near Fort Frances, where a dam has been installed, and where there is 14,000 horse-power available, inclines to side with the low-water adherents.

The Commission has been at work since early spring, and a Government decision establishing the water levels for the future will follow the presentation of its report.

THE POLLUTION OF THE NIAGARA AND DETROIT RIVERS.

Another important boundary matter receiving attention this summer is the degree of pollution of the Detroit and Niagara Rivers from the sewage emptied therein from the cities of Detroit and Buffalo, respectively. Being of mutual interest to Canada and the United States, the problem fell to the International Joint Commission, whose parties for both countries have been engaged for the past several months in investigation. The report, which will likely be completed within two months, will be a deciding factor concerning the various allegations of pollution. It may require considerable alterations to the present sewer systems of both cities. At any rate, the outcome of the investigation will be a valuable record of data that will be a fine addition to Canada's statistics concerning her international boundary waters.

PROVINCIAL ROADS IN ONTARIO.

The appointment of a commission to investigate fully the public highway situation in the older counties of Ontario, and to study all matters relating to construction, improvement and maintenance, is a second step in this important Government project. Although quite independent of the development work, of which Mr. J. F. Whitson is in charge in Northern Ontario, the two form a strong, progressive movement in the welfare of the province and its highways.

The plan to which the recently-formed Commission will devote its attention has long been under consideration. Six months ago it was announced in Legislature

that an appropriation was being considered for establishing a system of provincial roads, and the new Commission will define and regulate the amount of this expenditure. The Government is prepared to devote $10,000,000 to the enterprise.

The work in New Ontario has progressed satisfactorily, although handicapped by late snow and ice at the setting-in of the season. Many good pieces of road are in evidence for the small portion of the total expenditure of $5,000,000, some $250,000 of which will have been consumed by the time work ceases in the fall.

PATENTS AND THE ENGINEER.

Just how close a relationship exists between the engineering profession and the patent office is exemplified in a comparison of the terms in which both functions are defined. It is the common object of both to further civilization by the advancement of science and art. By its existence the patent stimulates creative and inventive ability, while the engineer exists to adapt the inventor's achievements to the use of mankind. The relationship, therefore, implies that the engineer, of necessity, must be familiar with the practical workings of the patent office.

This relationship is certainly not new, as the improved methods, machines and appliances of the age are, or have been, the subject of patents. Further, almost all engineering contracts and specifications include clauses contingent upon patent infringements and legal difficulties ensuing from such. Since these agreements constitute a phase of the engineering office production, the obviousness of a thorough knowledge of all exclusive rights associated with the work or the equipment used in construction is apparent. This knowledge consists chiefly in a clear understanding of what the inventor's rights really are, or, in other words, the scope of his patent; and of being able to distinguish the line of demarcation between the features of the work effected.

Patent law has come to be a profession in itself. It is a summation of specialties only contiguous to engineering in the above respect. But it is decidedly in the interests of the engineer to be clear in his ideas of the *modus operandi* and nature of patent office practice and patent litigation.

THE INTERNATIONAL GEOLOGICAL CONGRESS.

The Toronto session of the International Geological Congress opens to-day in Convocation Hall, University of Toronto, and continues for one week. The first series of excursions (12) is at an end, and all roads lead to Toronto.

At the meeting the chief topics for discussion have been selected as follows:—

(1) Coal Resources of the World.

(2) Differentiation in Igneous Magmas.

(3) The Influence of Depth on the Character of Metalliferous Deposits.

(4) The Origin and Extent of the Pre-Cambrian Sedimentaries.

(5) The Sub-divisions, Correlation and Terminology of the Pre-Cambrian.

(6) To What Extent was the Ice Age Broken by Interglacial Periods?

(7) The Physical and Faunal Characteristics of the Palaeozoic Seas, with Reference to the Value of the Recurrence of Seas in Establishing Geological Systems.

The session will be further enhanced by reports of committees of previous congresses, and by ten excursions to points of geologic interest in older Ontario.

The congress does not terminate with the close of the Toronto session on August 14th, but continues, in the form of lengthy excursions, the longest of which, extending into the Yukon, ends at Vancouver on September 22nd.

EDITORIAL COMMENT.

Attention is called to a change of name in one of our prominent technical societies. The Board of Directors of the National Association of Cement Users announces an amendment of the organization's charter, changing the name to American Concrete Institute. The association was founded in 1905, and since that time has done a great deal in the interests of cement and concrete. The nine conventions which were held during this period furnished much of the advanced and authoritative knowledge of the various applications to which cement has lent itself. The new name, American Concrete Institute, applies infinitely better to the activities of the organization than the old.

* * * *

It may be that one of the greatest discoveries in chemistry, possibly leading to the solution of the fundamental problem of the science, the nature and relationship of the elements is the production of Helium and Neon by electrical discharges in an atmosphere of hydrogen. Under suitable conditions, these and other elements, of a heretofore unknown character, have repeatedly been obtained, these results indicating a transmution of elements or a synthesis or a combination of both. They are the results of a series of investigations by Professors Collie and Patterson, University College, London, Eng.

SOME WANTS OF MUNICIPALITIES.

In an address given by Mr. J. N. Bayne, Deputy Minister of Municipal Affairs for the Province of Saskatchewan, at the thirteenth annual Convention of the Union of Canadian Municipalities, held in Saskatoon two weeks ago, reference was made to the absolute need of technical men in rural municipalities.

Among the appointed officials there is always need of the technical man, be that officer a road foreman, inspector, engineer, secretary, assessor or treasurer. Very often a rural municipality cannot, or may be under the impression that it cannot, afford to hire a skilled man as engineer for the laying out of proposed improvements. In a new country professional men of the kind are often scarce and their fees apparently high, so that as a result much experimenting with municipal public works is the result, costly in the extreme, and demonstrating the fact that proper preparation by way of securing competent advice at the start is highly advisable. Technical services are a want, therefore, in many rural municipalities, but fortunately this is being speedily overcome. Its absence is often simply the temporary lack of funds with which to meet the expense.

Another want which Mr. Bayne mentioned is the lack of continuity in the policy of the organization con-

cerned. This is due in the majority of cases to the constantly changing council boards. Too often a ward of division is represented for five years by as many different councillors.

Still another want which should not be overlooked is the knowledge on the part of every ratepayer, whether resident or non-resident, that he is an integral part of the municipal institution. That the business of the organization is his business, that he is a partner in a mutual co-operative benefit establishment. In speaking of the municipality and its officials he should learn to use the term "we" instead of "they." Mr. Bayne in closing gave a general statement or two regarding municipal development in Saskatchewan, now the third largest province in confederation.

On September 1st, 1905, the day on which Saskatchewan first came into being, there were only two rural municipalities, whereas to-day we have two hundred and ninety. Sixty-three villages have increased their number to two hundred and fifty-five. There were sixteen towns on the first mentioned date, now there are seventy-two; three cities were in existence on September 1st, 1905, and to this number was added Saskatoon in May, 1906, and in the same month in 1913 North Battleford became a city, and thus reached the highest possible municipal status for any organization to attain.

THE ECONOMIC POSSIBILITIES OF THE OVERSHOT WATER WHEEL.

The turbine in some form has so completely replaced all other motors in water power development that no other type of water wheel comes to mind ordinarily when water power is being considered. The overshot water wheel, for example, in the thought of most engineers, we presume, ranks as an obsolete device. This would be particularly so in America. Yet we are told of frequent use by German and French engineers of overshot water wheels for small water power plants, and the presumption is that their use has been found satisfactory and economical. This presumption is sustained by tests conducted at the University of Wisconsin and described by Mr. G. R. Weidner in a bulletin recently published by the university. Much of the discussion and the refinements of data contained in this bulletin are for the engineer versed in hydraulic motor engineering, but the main facts brought out are facts for the civil engineer to keep in mind, and are concisely given by "Engineering and Contracting" in a recent issue.

The results of the experiments show the overshot wheel to be a very efficient type of hydraulic motor, which, within certain limits is capable of rendering an efficiency quite equal to that of the turbine or even greater. It is the opinion of the author that, with a properly designed overshot wheel, operating under favorable conditions, the efficiency, computed on the basis of the output delivered at the wheel shaft, may be as high as 90 per cent., or even more. The conclusion has been reached from the fact that 89 per cent. was actually obtained in the experiments on a 10-ft. wheel, and that the Franklin Institute experiments showed an increase in the efficiency, although small, with the diameter of the wheel. Under the ordinary conditions of operation, this efficiency would be reduced somewhat to allow for the clearance between the wheel and tail water, so that 85 per cent. may be considered as a conservative estimate of the efficiency of the overshot wheel, when properly designed and installed.

The economical field of the overshot wheel lies in developments which range approximately between 2 and 30 sec.-ft. discharge, with heads varying from 10 to 40 ft., corresponding to a maximum development of about 75 horse-power. Within this field, the question whether to install a water wheel or turbine must be decided on the basis of the particular conditions of the power to be developed, the class of machinery to be operated, and the cost of installation. Only a rough approximation can be made as to the cost of the two types of motors, from the figures furnished by the manufacturers. In general, it may be said, that the overshot wheel, up to a diameter of 16 ft., will cost about double the amount a turbine of equal horse-power would cost, and above that diameter it will cost little more than double.

The peripheral velocity of the overshot wheel, when operating efficiently, varies approximately between 3 and 7 ft. per second, depending on the diameter, discharge, and velocity of the entering water. It is, therefore, particularly adapted for the operation of slow-speed machinery, and should find a field of usefulness, for the operation of small factories, the machinery on farms or country homes, and especially for pumping plants, where the pumps may be connected directly to the wheel-shaft.

For the operation of high-speed machinery, a loss of energy of from 3 to 10 per cent. may be estimated to occur through the necessary gearing or belting. The principal application or use of water power at present is the development of electrical energy. In general, the opinion is held, that only turbines on account of their high speed are applicable for this purpose. A number of electrical plants, operated with water wheels, have been built, which are giving satisfactory service. The inertia of the heavy wheel and gearing provides a very uniform motion, and high efficiency at part load is a very desirable feature in electrical plants. It is a matter for the designing engineer to decide, which type of motor will give the highest total efficiency, for a plant of this kind.

The overshot wheel is not adapted to conditions, where there is a considerable variation in the level of the tail water, unless the discharge can be increased sufficiently to compensate for the loss of power due to submergence. The efficiency of the wheel is reduced materially with a submergence of only a few inches.

In view of its high efficiency, reliability, adaptability to varying discharge, and simplicity in construction, setting and operation, the overshot wheel is still a useful type of hydraulic motor, worthy of receiving the attention of, and consideration by, engineers who may have occasion to develop small water powers.

An interesting test was made recently in Massachusetts to compare the relative efficiency of stump-removing by dynamite and by a $135 stump-puller. One man did the blasting, while two with a pair of horses operated the stump-puller. The contest was started in the morning. By four in the afternoon thirty-three stumps had been removed by the former method. These ranged in size from 9 to 33 inches; all were clean of dirt and split so as to be easily handled. Meanwhile the stump-puller had extracted twenty-one stumps. These were not clean, nor were they split, in fact, it was estimated that an additional day would be required to put them in shape. Fifty-six pounds of 40 per cent. dynamite and sixty-one electric fuses were used. The cost, including time and materials, was $26.07.

The National Municipal League will hold its annual convention in the city of Toronto, commencing the 12th of November next.

HIGH-PRESSURE SPRAY TREATMENT OF ROAD SURFACES.

BASING his paper upon experiments with tars for road purposes, started as early as 1892, and the use of experimental spraying machines, the first of which he had devised in 1895, Mr. Thos. Aitken, county surveyor, Cupar Fife, Scotland, has published his observations in a recent issue of *The Surveyor, London*. His paper was not completed in time for inclusion in the International Road Congress communications, unfortunately. It sets forth a wide range of experiences with high-pressure spraying machines in surfacing, treating macadamized roads and in bituminous macadam construction. The following is abstracted from it:

The system of tar-spraying roads by machines has greatly facilitated the work and reduced the cost. It lessens wear and tear, prevents suction by pneumatic tires of vehicles travelling at a high speed, reduces dust in dry, and mud in wet weather to a minimum, and at the same time lengthens the life of a road. It is usual with one of these tar-spraying machines, working under favorable conditions, to spray from 2,400 to 3,200 gals. of tar per day. This represents on an 18-ft. road a length of 1.37 miles at the former figure and 1.66 miles at the latter.

A tar-spraying machine to be of really good service should be economical in operation, constructed to withstand the hard usage naturally expected from the nature of the work it undertakes, and be capable of traversing the roads at a fairly high speed in order that full advantage may be taken of the limited time available for these operations.

There is absolutely no penetration by the hand or gravitation machine methods on an ordinary macadam road unless the tar used is of a very poor quality, applied exceedingly hot, and the metalling is in a practically loose state, certainly not the best combination to attain success. Overheating of refined tar, and even of some tar-compos when applied to the cold road surface, brings about results which are disastrous sooner or later. The idea of raising tar to a high temperature repeatedly, as has often to be done, is brought about by the necessity of making it sufficiently liquid so that it can be manipulated by the gravitation machines or used in carrying out other methods of application without due attention being given to the fact that the quality of the tar is thereby impaired. A good quality of refined tar has in many instances been condemned through being badly handled by inexperienced persons.

Refined tar and "bituminous tar" heated, if necessary, by steam coils and sprayed by a high-pressure tar-sprayer effects beneficial penetration, providing the road surface is properly cleaned. The amount of penetration varies according to the description of binding used when the road was recoated last and its general condition at the time of treating with tar.

The writer has found it 1½ ins. to 1¾ ins. in depth in many cases, and in this connection it is not oil that is meant, but tar of the same binding quality as that on top of the road. Effective penetration, along with a good film of tar on the wearing surface, is just what is required, and, the whole being keyed, gives a waterproof crust. As surface spraying on important and medium-trafficked roads is of an annual or recurring nature, it is of great importance that, in the first instance, the penetration should be effective, even although a greater amount of tar per square yard be applied than that found necessary subsequently.

It is a significant fact, borne out by experience, that when recoating roads by the ordinary or waterbound method, and employing a binding material of a loamy-sand description, penetration is easy and effective compared with roads which have been repaired with road scrapings or other promiscuous matter as a binding material.

Surface spraying over many of the principal counties in Scotland has occupied the writer's attention for some years past, and more especially in East Fife, where he holds an official position. Certain roads under the writer's jurisdiction have been treated with a variety of tars, oils and other dust preventives.

Refined tar has unquestionably given the most effective and economical results for surface spraying existing roads from the dust point of view, and, in addition, has greatly reduced the cost of maintenance on these roads by reason of the penetration effected, which practically waterproofs the surface and, to a great extent, prevents internal friction and consequent wear of the road stones.

A section of the Dundee, Stirling and Glasgow road west of Cupar was recoated for 4 miles, and a portion of this road for a distance of ¾ mile was treated later on with refined tar in 1908, and again in 1909, and has not been sprayed since. The section beyond the tar-treated portion, or westwards, had to be repaired with a centre coating in 1911-12 to bring the surface into good repair in view of the numerous potholes then existing. The tar-treated section has not required any further attention or expenditure so far as repairs are concerned during the period in question. The cost of recoating and rolling the whole section was 7.55d. (15.1 cts.) per square yard, and surface spraying on the section mentioned was 1.85d. (3.70 cts.) for each application, which together equals 11.25d. (22.5 cts.) per square yard during the period up to December, 1912, or five years. This section beyond, or westwards, has cost, first in 1908, 7.77d. (15.54 cts.) and then, in 1911-12, 7.77d. (15.54 cts.) per square yard, or 15.54d. (31.08 cts.) per square yard, so that, assuming the tar-treated section wears out about the same time before renewal, compared with the other section, which to all appearance is most likely, the comparative cost for ordinary macadam and macadam treated with tar per square yard per annum is 3.11d. (6.22 cts.) and 2.25d. (4.5 cts.), or nearly 28 per cent. in favor of tar treatment.

On another road, the Dundee, Edinburgh and Glasgow road, 1 mile east of Cupar, the surface had similar spraying treatment, which was carried out in the spring of 1907 and early in the following year.

This section, or rather one side of it, was again sprayed with tar in October, 1908. On the latter occasion the tar-spraying was carried out to demonstrate the practical working of the tar-spraying machine to some road engineers from abroad, although the road did not actually require this application.

As it turned out, however, the second and third application had, combined with the previous treatment, very beneficial effects in so far that when the other portions of the road were recoated in May, 1912, the portion referred to did not require any repairs, it being then in excellent condition. Although the portion was at the footpath side of the road, embracing the water table, a considerable volume of traffic passes over it, as the road, being only 21 ft. in width, is made use of practically from side to side by overtaking and passing vehicular traffic. The cost of the three applications of tar and chippings amounted to 5.55d. (11.10 cts.) per square yard, while the cost of re-

newing the adjacent portion by ordinary macadam was 7.11d. (14.22 cts.) per square yard. This would mean a considerable saving when long stretches of road are taken into account, and in this case represents £77 per mile over six years, or £12.83 per mile per annum. The condition of the portion of the tar-treated road referred to is excellent, and may reasonably be expected to last as long as the newly coated sections, or a period of from five to six years. The traffic on this road is principally that of motor cars.

It is necessary, however, to state that, had the surface spraying mentioned been carried out at present-day prices, the cost of the three applications, in these successive periods, would have been 6.19d. (12.38 cts.) per square yard, which represents approximately a saving of £44, or £7.33d. per annum per mile of road at the width stated, and which would show a considerable saving on an extensive mileage.

These costs per square yard for surface spraying mentioned in the preceding page include haulage of the tar to the place of operation, heating, repairs to and depreciation on the machines, and the cost of the tar and application of same.,

In regard to fairly deep penetration, a road in the burgh of Newport, Fife, may be cited. The burgh engineer being desirous of thoroughly testing this point, and at the same time have a satisfactory surface, repeatedly washed the road to rid it of extraneous mud which had been incorporated in the crust at some previous time when the road was repaired and rolled. After the road dried out it was swept clean and the tar-spraying carried out in dry weather. The penetration was such that the tar practically disappeared, which appears remarkable, considering the fact that 1 gal. of tar only covered 4 sq. yds. The road was duly spread with chippings, but did not present a surface which was likely to satisfy the burgh engineer. On the advent of warmer weather, however, the tar was gradually drawn to the surface. The penetration in this case was fully 2 in., which could not possibly have been done with any other machine than a high-pressure one.

Similar cases could be described from data in the writer's possession of work carried out in and around Cupar Fife, but it may be more conclusive to describe some of the surface spraying carried out by Aitken's patent gold medal tar-spraying machine in another centre, the figures as to cost of maintenance and other details being given by the official in charge.

The road in question is an important one, leading from the city of Edinburgh to Queensferry, over which, especially during the summer months, a very heavy continuous traffic passes, including motor buses. The road for the most part is 40 ft. wide, and extends to about 1½ miles, and the whole surface has been sprayed annually in the beginning of May for the last three years, and certain portions for the past five years.

The annual cost of maintenance previous to the tar treatment, including all items except establishment charges, was, on an average, for three years previously, £440 per mile, or 4.19d. (8.38 cts.) per square yard per annum.

Since this thoroughfare has been tar-sprayed the annual expenditure for materials and labor has been reduced to £399 per mile, or 3.84d. (7.68 cts.) per square yard, which figure includes surface spraying. These figures represent a difference which is equal to .35d. (0.7 ct.) per square yard, or an annual saving on previous expenditure of 9¼ per cent., in addition to a considerable reduction in the cost of watering and cleansing. The cost of surface spraying on an average for three years was, for tar and application, sweeping and chippings, 1.92d. (3.84 cts.) per square yard.

It is necessary, however, to mention that this road was put in good repair previous to the first surface spraying, and the work was carried out in what the writer considers, and has always recommended, ideal methods of using 2-in. gauge metal with a binder of chippings—and it may be mentioned the latter material was produced from rock having stable constituent minerals—rolled and the surplus binding swept off. When the tar-spraying operations were commenced the road had been thoroughly swept, and was in a dry condition. The quantity of tar applied under these favorable conditions figures out at the somewhat excessive amount of 4.5 gals. per square yard, and it was remarkable how small a film of tar was apparent on the surface of the road immediately after the operations were carried out. On the advent of warmer weather, however, the actinic force of the sun's rays caused the tar to reappear, and, combined with the clean whin chippings applied, made an excellent surface, which was absolutely free from dust. This, the writer considers, is the proper condition in which a road should be for effectively waterproofing the surface, and which lays the groundwork for future spraying operations.

The writer considers the excellent condition of this road previous to being tar-sprayed, combined with the deep penetration effected, has been instrumental in securing the results obtained, and the surface spraying, which has been carried out annually, has maintained these economical results.

In carrying out surface spraying the thorough cleansing of the surface of the road cannot be too strongly emphasized as an important factor in obtaining successful results. The surface of the road for treatment must be cleansed of all foreign matter by repeated applications of a rotary brush, or otherwise, so that the surface be left as open as possible to permit of penetration, and so allow the tar to act partly as a binder, and not merely forming a "blanket coat," which has already been referred to.

In the course of the writer's experience he has many times seen a good quality of tar, properly applied, give but poor results, entirely due to inefficient preparation of the road for the application.

Spreading clean, uniform-sized chippings on the newly sprayed road surface is also a factor which assists in the attainment of satisfactory work, and should always be adopted. This important point has, however, apparently not been so well understood in some counties, as it is noticed from time to time in the technical journals, that road scrapings have been used considerably for this purpose. This is remarkable, and certainly cannot lead to success, and it is a matter of surprise to the writer that any road engineer permits such material being used.

These remarks, so far as possible in a paper so limited, practically conclude the writer's experience of surface spraying macadam roads from the point of dust prevention through the road crust being waterproofed by effective penetration of the tar. Unquestionably tar spraying, when properly carried out, is a very effective remedy against the formation of dust, and also lessens the excessive wear of the roads by vehicular traffic.

This has been abundantly proved by the cases cited in the preceding pages, which roads have been treated with high-pressure tar-spraying machines.

In addition it may be stated that the cleansing of roads properly treated by high-pressure tar-spraying machines is considerably reduced, and, in fact, in many cases

the cost of tarring is met by the reduced cleansing account, and in addition there are the economical results attained in the cost of maintenance.

Bituminous Macadam Construction.—In using high-pressure spraying machines for making tar macadam *in situ* the following operations are usually adopted: The road, previous to coating with metal in the usual way, is repaid in a superficial manner to make the surface fairly uniform, and approaching the contour which the new surface is intended to have when finished. All extraneous soft binding matter should be removed so as to present a clean, hard surface. When the moisture is dried out the surface, after sweeping, is sprayed with bituminous tar or other tar-compo, and ½ in. to ¾ in. whin or similar chippings applied so as to waterproof the old surface, and form a key on which the new crust is to be formed.

The metalling, preferably 1½-in. to 2-in. gauge, free from extraneous matter, is then spread to the desired depth—3 in. to 4 in. generally—and when a stretch of 30 yds. to 50 yds. has been carried out, and without being rolled, the "tar-spraying machine," with the atomized nozzles placed at an angle, commences at outside and works in 6-ft. to 7-ft. breadths until the surface is all sprayed. The machine is then reversed, and the spraying is carried out in an opposite direction. This effectually covers all the road stone surfaces, especially in the lower parts, as, being left in a loose state, the great pressure used in forcing the binder into the body of the metal coating covers all with a film of tar. When this has been carried out ½-in. to ¾-in. chippings are sprinkled over the surface and lightly rolled. The chippings work gradually down into the metal coating, practically filling, along with the binder, all the voids. Should any depressions appear these are made good before the spraying machine again travels over the portion first treated and gives two other applications of binder. Chippings are applied, and further rolling finishes the work, and, if necessary, more chippings are sprinkled over the surface. This generally completes the operation, but if a very smooth asphalt-like surface is desired an extra coating of binder may be applied. In all 1-25 to 1-50 gal. per square yard are sprayed, depending on the depth of the metal coating, and description of the road stone used.

In carrying out this class of work, especially in the earlier stages, some curious results have been experienced, insofar that even when using the same road material and binder on a stretch of road of an apparently uniform nature certain small portions or patches became very unsatisfactory at varying periods after construction. These defects evidently pointed to bad subsoil drainage, but, as it turned out, it was invariably due to this combined with the presence of clay which apparently had not been specially treated when the road was originally made.

It has been the writer's practice when making new roads to separate any portion or even pockets or patches of clay from the road proper by laying a bed of hard engine ashes or clinkers, and in some cases gritty sand.

It is well known what bad effects a clay subsoil improperly drained and not specially treated has in the maintenance of an ordinary macadam road. It is doubly so with tar-macadam, as when the surface breaks up, even in isolated spots, the advent of rain permits of percolation, and the moisture spreading on top of clay with no possible means of escape except upwards by evaporation increases the area of the patches originally affected, and spreading practically ruins the whole surface.

The few exceptions mentioned previously were brought about by this cause. Roads which are to be made of tar-macadam, no matter by what process, should be carefully examined by making trial pits, and the nature of the subsoil recorded as a guide in carrying out the subsequent operations, so that uniform and satisfactory results may be obtained. The most satisfactory work is obtainable when the formation is of sand or gravel, as the subsoil drainage under such conditions is practically perfect and cannot be improved upon.

The character of the road stone is a factor in making tar-macadam. The writer, after many years' experience in using most kinds of igneous rocks, considers that the material which has a rough or coarse grain when broken into road metal gives the best results. This roughness gives a keying power and holds, along with the binder, the whole coating firmly together. It is a significant fact that less binder may be used and that less rolling is necessary, or, in other words, more work can be accomplished in the same time by using such materials.

Basalts, dolerites and gabbro generally, if the constituent minerals are in a fresh condition, prove satisfactory materials for tar macadam, and along with these certain granites. Andesites, on the other hand, having a dense, fine-grained texture, and with other similar descriptions of stone, are not so good and generally require a greater amount of binder to obtain good results. Further, should rolling operations be commenced immediately after the spraying is finished, the individual stones slide one upon another, and it is difficult to keep the road in proper section. Under these circumstances it is better to leave the tarred section for some time to permit of the binder partially setting before rolling is commenced. The writer has observed roads apparently left in good order become somewhat uneven during very hot weather, and this undoubtedly has been brought about by using too much binder. In some cases this has, along with the use of road stones of the andesite family, prevented sufficient frictional resistance to maintain the road in a stable condition.

The proportion of aggregate and matrix forms an interesting factor in construction, initial cost and future maintenance entering largely into the matter. The voids in a coating of 1½-in. to 2-in. metal spread loose amount to practically 46 per cent., and when consolidated the total volume will be reduced, including, say, 10 per cent. of chippings and the binder itself, to a density or solidity of from 86 to 90 per cent., the difference being taken up by air spaces.

It is the writer's opinion that if the proportions of aggregate and matrix are properly adjusted, according to location and traffic conditions the tar-macadam crust should, providing all other circumstances are favorable, form a roadway capable of being looked upon as a foundation, and the actual wearing surface may be renewed from time to time by the application of a bituminous material of recognized quality, such as Trinidad asphalt. Therefore, according to traffic conditions, the road crust never need be renewed. It is understood this is possible, providing the foundations do not give way, and that the subsoil drainage is kept in perfect working order—a matter, however, which requires constant examination and careful supervision.

In comparing the cost of tar-macadam in different centres the fact that the specific gravity of the stone is seldom mentioned when the amount of binder is stated at so much per ton of material applied is very misleading. This point should be very carefully kept in view when figuring out detailed particulars, as the following instances will show. In the county under the writer's juris-

diction the specific gravity of road stones varies from 2.49 to 2.99, the former being a felsite and the latter an ophitic dolerite. The respective covering power per ton of these two materials varies considerably, as in the former 1 cu. yd. = 20-61 cwt.; therefore, 1 long ton will only cover 7-37 sq. yd. As the covering power of 1 cu. yd. of metalling at any given depth is the same under any circumstances, it follows that in the case of a stone having a lighter specific gravity, the amount of binder per square yard would be, for a coating 4 in. in depth, 1.26 gals., and in the case of the heavier stone 1.50 gals. per square yard—quite a significant difference when large areas are under consideration. In addition to the specific gravity being given, it is also desirable to state the amount of binder used per square yard for a given depth of metalling when spread loose, or if consolidated the gauge of the material used in the coating, as consolidation varies to an appreciable extent in coatings composed of different gauges of stones. Statements as to cost would then have some comparative value, and this would save considerable trouble in investigating work carried out in various centres throughout the country.

Tar-macadam carried out with ordinary bituminous tar and such like compositions requires that the wearing surface be renewed every two to four years, according to the amount of traffic and the nature of the metalling employed when carrying out the work. In such operations coarse-grained stones will proportionately require to be treated every two to four years compared to one and two years when fine-grained stones are used.

The method of renewing such surface is very easily accomplished. First of all, should there be any serious depressions, these must be repaired by applying a suitable oil and filling in the pothole with a small quantity of bituminous tar, and level up with ¾-in. chippings. When these patches have set properly the whole surface must be thoroughly swept and then sprayed with a good coat of suitable binder, ½-in. to ¾-in. clean chippings being spread over the whole area and treated and then rolled. A more effective method of performing this operation, especially if the weather is not very hot, is to spray a small quantity of oil on the surface and allow it time to soften or revivify the old binder material, and then apply a good coating of the bituminous or other suitable composition, apply the chippings and roll solid. These operations, as already mentioned, require to be carried out periodically, and by so doing the original tar-macadam road is effectively renewed for traffic at a comparatively cheap rate compared with reconstructing the whole road crust should it be allowed to get so far out of condition that such measures become necessary. Tar-macadam carried out as described in the preceding pages presents a smooth, uniform surface, which is waterproof and slightly resilient, very important factors in modern road construction.

A German inventor, Carl Canzler, has a process of welding copper with oxy-acetylene flame whereby his torches, according to the "Scientific American," are larger than the ones used for the welding of iron. He also employs a liquid welding paste to prevent the formation of an oxide. It is claimed that copper plates up to one inch in thickness have been welded. The joint formed will withstand acid, it is said, and is as strong as a continuous copper sheet of solid metal. This new process is being used with success in the principal copper works in Germany.

FORCEFUL APPLICATION OF CEMENT.

Owing to the menace of teredos and liminoria to wooden piles, untreated piles having been eaten through in three years and creosoted piles having fared but little better, great ingenuity has been exercised to devise some permanent and satisfactory way to protect wooden piles from the ravages of these pests.

Inventions along this line have included sheet copper coverings, plaster coatings, covering with concrete, wrapping with burlap and compounds, and innumerable other devices, all of which have proven too costly or ineffective for one reason or another.

The most promising line of endeavor, and along which most attempts have been made, has been concrete coatings, and the best results, so far, have been obtained by applying this coating of cement-mortar to the pile for a portion of its length, extending from below the mud line to high water, with the aid of a cement gun.

Mr. Rudolph Hering suggested another important use of this apparatus in a report he made concerning the repair of a Nashville, Tenn., reservoir. He recommended its use as a means of applying a coating to prevent leakage through the walls of the structure. A portion of his report dealing with this is as follows:—

"In order to secure watertightness of the present walls they should receive a lining of cement mortar over the entire inside surface of the reservoir, applied by what is known as the cement gun. Wet cement mortar of a proper mixture is shot against the surface of the wall, after this has been thoroughly cleaned, first by thorough washing and scraping, then by sand blasting, which will make the adhesion of the cement complete. The density of this gun cement is very great, and it penetrates into all open crevices and covers every fine crack. An average thickness of about an inch is more than enough to make a wall entirely watertight."

Micrometer measurements in thousandths of an inch are no longer rare, and even the ten-thousandth is quite determinable. Far beyond this is the sensitiveness of the new electrical machine described by Dr. P. E. Shaw to the British Institution of Mechanical Engineers. It depends upon the principle of electrical touch, has the quarter-millionth of an inch as its unit, and is adapted for a variety of measurements of cylindrical, spherical or parallel-faced bodies. In engineering gauges of great precision it has shown errors of something like the one-hundredth-thousandth of an inch.

When excavation and construction work is carried on at night the results obtained are in many cases vitally affected by the character of the illumination provided. So well understood is this factor of night work efficiency that even among contractors who do not utilize electric drive, electric lighting is being very generally adopted when the working area is located in or near a zone of electric current distribution. For this class of service the use of long life flame arc lamp insures a maximum illuminating effect for a given current consumption, while the simplicity and strength of the mechanism will minimize outages and the cost of cleaning and trimming. This lamp can be supplied for operation on either alternating or direct current circuits, and is especially designed for outdoor service and the illumination of large areas. On the Panama and New York State barge canals electric searchlights have been advantageously used for directing night operations and for concentrating illumination at distant points where the use of ordinary lighting units would be impracticable.

THE OTTAWA RIVER STORAGE SYSTEMS

A SCHEME TO STEADY THE FLOW FOR THE PRODUCTION OF POWER—TO INCREASE THE DEPTH FOR PURPOSES OF NAVIGATION AND TO IMPROVE THE POTABILITY OF THE WATER.

By J. A. MACDONALD

HYGIENIC experts agree that the extreme low level of the Ottawa River at certain times in the year is a big contributing force, not only to the diminution of the capacity of the scores of water-powers on the river, but also, and probably to a more serious extent, to the health of the people living contiguous to the river. It is conceivable that with the subsidence of the full flow of the steam, deposits of deleterious matter are scoured by the shallow currents, and carried into the intake pipes of the various waterworks systems drawing their supply from the Ottawa. At all events, the sedimentary pollution would be delivered in a more concentrated form under such conditions than if a normal level had been maintained. And it is an observed fact that, the occurrence of sickness due to impure drinking water synchronizes with the periods of extreme low water in the river. This is particularly true of the city of Ottawa.

It is now over four years since work was begun on a scheme of conservation of the waters of the Ottawa by means of reservoirs created by the construction of dams at the outlets of several of the large lake expansions on the upper reaches of the river. The first, upon which considerable progress has been made, is situated at the foot of Lake Timiskaming. To store the waters of the Kipawa, a tributary of the Ottawa flowing into Lake Timiskaming, another dam is being built, and about fifteen miles above the head of the Timiskaming on the reach of the Ottawa, known as the Quinze, a third dam is in course of construction. This dam will store the waters of the Quinze and Expanse Lakes. The execution of these important works has been placed by the late Minister of Public Works in charge of Mr. C. R. Coutlee, C.E., a leading authority in hydraulics, who has made an exhaustive survey of the drainage areas of the Ottawa and its tributaries, and who has been given direction of the entire storage scheme.

Fig. 1.

Measurement of the flow at the Chaudiere Falls shows that at extreme spring flood 150,000 cubic feet per second goes to waste over the falls. At extreme low water the flow declines to 10,000 cubic feet per second. To prevent the waste in spring and utilize it to augment the diminished flow in the low water period is the object of the storage system.

filled up with a reserve supply. This can be fed out during November, December, January, February and March, thereby doubling the present insufficient low-water flow."

A stream 100 feet wide and 3 feet deep, running at the rate of 1 foot per second, or ⅔ mile per hour, would practically fill one square mile a foot deep in 24 hours;

Fig. 2.

In a progress report upon the Ottawa River Storage System, Mr. Coutlee says: "The capacity of each of the three lakes, Timiskaming, Kipawa and Quinze-Expanse, is about 100 square miles in extent and a layer 20 feet in depth stored in them would be 2,000 square mile feet of storage. Altogether, then, their storage would amount to a depth of one foot over 6,000 square miles. It would

or, more exactly, 322 c.f.s. will fill or empty a square mile one foot deep in one day.

It is further estimated that perfect control would require a constant flow of 31,000 cubic feet per second, and that this can be obtained by a further system of dams which will remain and regulate the waters of the numerous lakes and tributaries of the Ottawa between the

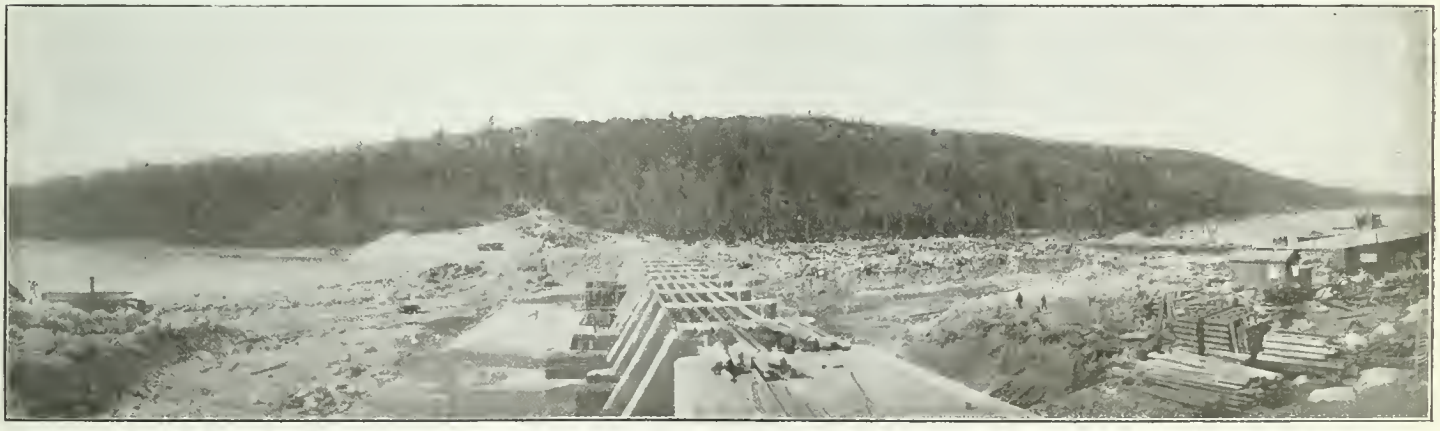

Fig. 3.—Timiskaming Dam, Ontario Side.

take a flow of 18,000 c.f.s. to empty the three reservoirs in 100 days, or a flow of 12,000 c.f.s. to empty them in 150 days—the average low-water period of the river. If we encroach upon the spring flood and allow only a normal flow to pass, these three great reservoirs will be

Quinze-Expanse basin and the source of the river. These include Lakes Opasaica, Grand Lake, Victoria, Barriere, Kakabonga, etc., which would give an additional 5,000 square mile-feet of storage. Although, measuring across country from the head of Lake Timiskaming, the Ottawa

and Gatineau are over 200 miles apart, they take their rise within a mile or so of each other about 150 miles north of Ottawa city, and at Kakabonge Lake they are so close together than an arrangement can be made there to divert a considerable part of their contents towards Hudson Bay in case of need.

Fig. 4.—General View Timiskaming Storage Dam, Ontario Channel, Looking West.

"Investigation shows," says Mr. Coutlee's report, "that several lakes can be economically converted into reservoirs by dams at the outlets. The flood water, then, instead of rushing to waste, would be pent up in these reservoirs, and gradually let out later in the season. These reservoirs will exert a three-fold effect upon the discharge of the drainage basin, as follows: 1, Improve the potability of the water; 2, increase the depth for navigation; 3, steady the flow for power production."

While in the foregoing summary of advantages to be derived from the proposed storage system probably the most important is the beneficial effect upon the quality of the water, it was evidently not the intention of the engineers in charge to intimate that regulation of the flow would convert the Ottawa River into a safe and dependable source of water supply for the various towns and cities situated along its banks.

The St. Lawrence is a vastly larger stream than the Ottawa, with immense settling basins, and flowing over a limestone bed which tends to clarify its water. Yet, it is well to mention in this connection that Toronto is obliged to filter the St. Lawrence water, although taken outside the Island.

The supply of the Ottawa is too large to heat, but not large enough to prevent contamination. The increased and uniform flow to be secured by the construction of the conservation works, now well under way on the Upper Ottawa, will bring about the only improvement in the water supply that can be counted upon for some time to come.

The Main Object of the Work.—It was chiefly with a view to improving the navigation and steadying the flow for power production that the conservation works were originally planned. While only the source of supply and storage which are available from Lake Timiskaming upward are yet being dealt with, it is the intention of the government to have surveys made of the drainage areas of all the tributaries of the main river, so that eventually their entire capacity may be rendered available for purposes of power generation and transportation. The magnitude of these latent resources may be grasped when it is considered that the Ottawa basin is 56,000 square miles in area, and contains the grandest aggregation of lakes and streams of any similar area in the known world. Ten thousand square miles of this lies south of the river and is drained by the Petawawa, Bonnechere, Madawaska, Mississippi, Rideau and South Nation Rivers. Five thousand square miles drain into the main stream through small tributaries. Forty thousand square miles lie north of the river. The Dumoine, Black, Coulonge, Gatineau, Lievre and Rouge Rivers drain 20,000 square miles, which includes the drainage area above Mattawa, forms the upper basin.

The scheme is, briefly, to dress the river up in convenient reaches by large rock-fill dams provided with sluice openings to pass the flow from basin to basin, locks being provided at each dam. It would be possible to build the dams required at any point as soon as the reservoirs are completed, and offer, in advance of a navigation

Fig. 5.—Timiskaming Storage Dam, Showing Method of Drilling Boulders Under Water; Dynamite is Loaded into the Drill Hole Through a Gas Pipe, and Exploded by Electric Battery.

project, sites for power development with a guaranteed steadiness of flow, and a constant head without ice difficulties. The river being thus arranged by dams, power can be developed on a general scheme, which could be enlarged to utilize the whole flow at each point in years to come, when transmission may convey to unheard-of distances, and when large blocks of power will be required for heating, for nitrogen fixation from the atmospheric air (now an engineering commercial enterprise except for the expense), for smelting, and for electro-chemical processes.

THE THIRD INTERNATIONAL ROAD CONGRESS, LONDON, 1913.*

By Arthur H. Blanchard, M. Am. Soc. C.E., Professor of Highway Engineering in Columbia University, and Consulting Highway Engineer, New York City.

"STOP, Look and Listen," the characteristic sign which attracts the attention of the traveller at crossings of highways and railways throughout the United States, contains advice of inestimable value to those interested in the development of highways. As a pertinent citation of its application, the work of the third International Road Congress is worthy of careful study in order that the mass of information collated through the medium of reports, discussions, conclusions and exhibitions may be drawn upon to furnish ideas which may be used in the development of highway engineering in this country.

To-day, the world appreciates the admirable work instituted by the French Government in 1908, through the medium of its famous Department of Roads and Bridges in calling to Paris highway engineers and officials from all over the globe for the purpose of mutual exchange of opinions pertaining to the administration, construction, and maintenance of highways. At this convention the First International Road Congress, steps were taken to form the Permanent International Association of Road Congresses.

The Association includes in its membership national governments, state governments, municipalities, associations and societies, companies manufacturing materials and machinery, and individual members. According to the 1913 report of the Executive Committee of the Association, the membership on May 31st included 32 national governments, 256 corporate bodies and 944 private members. The dues of these members for the year ending May 31st, 1913, were $21,520, of which $14,980 was subscribed by national governments.

Of particular interest to the citizens of the United States are the regulations relative to the affiliation of national governments. The pertinent portions of the regulations pertaining to the two controlling bodies of the Association, the Permanent International Commission and the Permanent Council, are as follows:—

"The Permanent International Commission is composed of members belonging to the various countries represented in the Association. Each country has the right to one representative for each $200 of its total annual subsidy. Provided, however, that the number of representatives from any one country shall not exceed fifteen, and that any country which pays not less than $50 shall have the right to appoint one delegate.

"The Permanent Council is composed of representatives chosen from among the members of the Permanent Commission: one for each country whose annual subsidy does not exceed $100; two for each country whose annual subsidy exceeds this amount, and is less than $2,000; three for each country whose annual subsidy exceeds $2,000."

It is unfortunate that our national government stands alone among the great governments of the world in not having affiliated with the Permanent International Association. Our neighbors, Cuba and Mexico, are among those who have led us in officially expressing the interest of their national governments in the improvement of highways.

Since 1908 the subject of affiliation has been under consideration in the United States, and since the Second International Road Congress, held in Brussels in 1910, an active campaign has been waged to secure the adherence of the United States. In order that the United States may take its proper and dignified place in the world-progressive movement conducted under the Association, it appears the duty of every Association interested in good roads to pass resolutions memoralizing the Congress of the United States to take the necessary steps to become a member of the Permanent International Association of Road Congresses.

During the sessions of the Third International Road Congress held in London in June, 1913, it was decided to accept the invitation extended by the German Government to hold the 1916 Congress in Munich. Since the Brussels Congress there has been a tacit understanding that the Fifth International Congress should be held in the United States in 1919. It is, of course, obvious that unless the United States becomes a member prior to 1916, it will be practically impossible to carry out this very desirable programme, desirable not only from the standpoint of the citizens of the United States, but also from the standpoint of highway engineers and officials in all the countries of the world.

A brief outline of the scheme upon which is founded the work of an International Road Congress will give some idea of the large amount of available information relative to every phase of highway engineering which is disseminated among highway engineers and officials throughout every land. The Permanent International Commission, about two years in advance of a Congress meeting, decides upon a series of topics which it considers of vital importance, and upon which a large amount of investigative work is in progress. Another series of topics is selected pertaining to subjects upon which thought has not crystallized as definitely as in the case of the first set of subjects, but information in regard to which will serve as the basis for future concentrated and co-operative work. The first set of topics is defined as Questions, the second set as Communications. The Executive Committee of the Association then notifies the national representatives in various countries of the list of Questions and Communications, and requests that in each country a reporter, or a group of reporters, be designated to prepare a comprehensive review on each Question and upon each Communication, the viewpoint in each case being national. The reports are delivered to the Executive Committee some six to nine months prior to the meeting of a Congress, are printed in the three official languages of the Association—English, French and German—and distributed before the opening of the Congress to all members of the Association. In the country in which a given Congress is held general

* Paper presented before the Convention of the North Carolina Good Roads Association at Morehead City, N.C., August 1st, 1913.

reporters on each question are appointed to review all reports submitted, to summarize the practice indicated, and to draft a set of conclusions which represent the majority opinion relative to various essential phases of each subject. These general reports are supposed to be distributed prior to the meeting of a Congress. The business sessions of the various sections of a Congress are devoted to a consideration of the conclusions submitted by the general reporters. Naturally, many amendments are proposed before the conclusions are finally adopted by the section particularly interested in a given subject. The conclusions as reported by the various sections are submitted at the final general meeting of a Congress, where they are considered for final adoption. The discussions, conclusions, general work of the Congress, and a description of the excursions, entertainments and the exhibition are published as the Proceedings of the Congress.

At the Third Internation Congress a total of 140 reports was presented by reporters from nineteen national governments, nine Questions and ten Communications composing the programme. Nine general reports by British engineers were prepared relative to the Questions. The meetings of the Third Congress were well attended, the total attendance being between 2,500 and 3,000. The Congress was so conducted that the proceedings of the various sessions, although carried on in the three official languages of the Congress—English, French and German —were interesting and instructive. By having present expert interpreters, those in attendance were made acquainted with the remarks of members from all countries without any material delay in the progress of the meetings.

The exhibition was divided into four divisions: road materials and machinery; traffic; models, maps, drawings and publications; and historical data. The first division comprised 42 exhibits of the principal types of materials and machinery employed in Great Britain and on the Continent.

The practical influence of the Congress on the development of administration and organization of highway departments and the improvement of roads and pavements will depend to a marked degree upon the extent of the adoption of the principles and recommendations contained in the conclusions of the Congress. The conclusions, although expressing in many instances the fundamentals of modern highway engineering practice, nevertheless will repay careful digestion by every American interested in good roads. Unfortunately, American engineers and highway officials have not universally adopted many of the fundamental principles laid down at the International Road Congresses. Among the 83 conclusions adopted at the Third Congress, which are of especial interest to those having charge of highway work in the United States and Canada, are the following:—

First Question—Planning of New Streets and Roads.

"As a general principle, it is better that new main roads be constructed to pass outside rather than through towns, and that, where an existing main road passing through a town is unsatisfactory for through traffic, it is often better in preference to widening an existing narrow main road through the centre of a town, new roads should be planned according to the principles of the science of town planning.

Second Question—Types of Surfacing to be Adopted on Bridges, Viaducts, etc.

"On short bridges in town or country it is desirable that the surfacing should be the same as that on the adjoining streets or roads.

Third Question—Construction of Macadamized Roads bound with Bituminous (including Tarry and Asphaltic) Materials.

"Confirming the conclusions adopted in 1910 by the Second Congress (Brussels, second question), which called attention to the advantages of a dry foundation and a sound subsoil, the Congress especially insists upon the great importance of efficient foundations in the case of road crusts bound with bituminous (including tarry or asphaltic) binders for the following reasons:—

"The road crust being expensive, it is important to give it a base which will increase its life.

"As the weight, speed and intensity of the traffic continually tend to increase on roads considered worthy of such a crust, it is best to provide a foundation which has been so constructed as to secure for the crust the best possible conditions of resistance to wear.

"It is agreed that it is absolutely necessary to carry out repairs, in the case of all bituminous (including tarry and asphaltic) road crusts, immediately the necessity for them arises.

"The complete renewal rendered necessary by wear must be carried out immediately the depth of the road crust is below a given limit of safety, or when its waterproofing qualities have become so poor that the road will unduly suffer from climatic conditions.

"In the mixing method the stone must always be dry, and if necessary it must be heated.

"One must never employ road rollers which are too heavy.

"Sufficient information is now available to enable engineers to select and specify bituminous binders which will have no prejudicial effect upon public health, fish life, or vegetation; but which, on the contrary, will conduce to conditions of considerable hygienic advantage.

Fourth Question—Wood Paving.

"Hard woods give varying results, according to local circumstances, and it does not appear desirable to recommend them for roads with intense traffic in large cities, unless some means are devised to effectively prevent the rapid destruction of the joints and the resulting destructive effect on the concrete below.

Fifth Question—Methods of Lighting.

"Every vehicle, whether standing or moving, should carry or show a light of sufficient power at night which can, except when specially authorized, be seen from the rear as well as from the front of the vehicle.

"Every motor car must carry after nightfall two lighted lamps in front and one at the back; if it is able to move at a high speed it must be fitted in front with a headlight of sufficient illuminating power to light up the road or path for at least 50 yards to the front. In inhabited places, where the ordinary lighting is sufficient to allow motorists to see their way and to be easily seen, the light of the headlights must be limited to that of the ordinary lamp.

"One and the same color should be universally adopted as the color for danger signals.

"It is desirable that each Government should do away as soon as possible with colored lights on automobiles.

Seventh Question—Regulations for Fast and Slow Traffic on Roads.

"That all regulations for the control of road traffic should be based on the principle of allowing the speed practicable for each different kind of vehicle consistent with public safety, general convenience, and the normal wear of the road.

Eighth Question—Authorities in Charge of the Construction and Maintenance of Roads—Functions of Central Authorities and Local Authorities.

"A principle that can be laid down as of universal application is, that the unit of highway administration shall be sufficiently large and command sufficient resources to employ and adequately remunerate a competent staff.

Ninth Question—Finance of the Construction and Upkeep of Roads—Provision of Revenues.

"The expenditure on the maintenance and improvement of roads which are used mainly by long-distance traffic, unless such expenditure is borne wholly out of the national revenues under a system of State administration of roads (which system is practicable and suitable in the case of some roads in some countries) should be mainly paid for out of national revenues, whether or not such roads are locally administered and maintained, subject, where local administration prevails, to the supervision of a central government authority, both as to efficiency and expenditure.

"It is desirable to abolish, so far as possible, all tolls on public roads, but it is equitable that vehicles which, on account of their weight or weight combined with speed, or any other exceptional circumstances connected with either the vehicle or use of the road, cause special damage to roads beyond the wear and tear of the ordinary traffic of any district, should be subject to special taxation the proceeds of which should be earmarked for expenditure on roads.

"Borrowing money for new road construction and for the periodic renewal of the surface coating of a road is consistent with sound financial principles provided that the loan period in the case of loans for renewals, is kept well within the life of the surface coating."

Even a brief summary of the work of the Third International Road Congress should not be closed without reference to the hospitality and elaborate series of entertainments and excursions provided by our British cousins and the officials of the Permanent International Association of Road Congresses.

A new generating station will be opened shortly at West Hartlepool, England, which claims to be the first municipal authority to produce electricity by means of waste heat, says a Consular report. The two turbo-generators, each of 1,500 kw., will be driven by exhaust steam from the furnace-blowing engines of the Seaton Carew Iron Co., adjacent to whose works the station is built. In return for their exhaust steam, which has hitherto been blowing to waste in the air, the Seaton Carew Iron Co. will receive current free from the corporation. Expenditure on coal will practically be eliminated. The coal bill for the present electricity station is about $20,000 a year, and, as it is anticipated that the consumption of current will largely increase under the cheaper rate now possible, the ultimate saving by the use of waste heat will be very considerable. Should the supply of exhaust steam not be available, either through a breakdown of the blowing engines or through the iron works being idle, a supply of high-pressure steam will be obtainable from the Seaton Carew Iron Co. The total expenditure involved in connection with the new scheme is $188,500, the plant alone having cost $150,000. The old generating station will be maintained as a stand-by and as a town substation. There the current from the new station will be transformed to the voltage required for distribution to the town.

SPECIFICATIONS FOR FUEL FOR HEAVY-OIL ENGINES.

THE United States Bureau of Mines has carried on a careful investigation to ascertain some means of more effectively burning heavy asphaltum oils as fuels for steam raising and for internal-combustion engines. The result of the extended search appears in pamphlet form as a bulletin recently issued, and entitled "Heavy-Oil as Fuel for Internal-Combustion Engines," by Irving C. Allen. From this investigation the consensus of opinion seems to be that an oil, to be burned with success in these engines, should possess the following characteristics:—

Solidifying Point.—The oil should be mobile at 0° C. If it be heavy or viscous or contain a considerable proportion of asphaltum or paraffin, it will become sluggish and stiff at low temperatures, and considerable heat will have to be used to warm it before it can be run into the engine.

Fluidity.—Sluggish oils should first be heated before being introduced into the engine. If it be necessary to use very heavy oils, the engine should first be warmed by running on a more fluid fuel and the heavy oil introduced only after the engine is hot and running well. This process should be reversed when shutting down, and the heavy oils should be washed out of the engine valves and pipes with a lighter oil, the engine being run a short time on one of these lighter oils before it is allowed to become cold.

Tar Content.—An oil should contain not more than 0.4 per cent. of material insoluble in xylene, as a larger proportion of insoluble material will tend to form coke in the cylinders. (Ten grams of the sample mixed with 10 cubic centimeters of xylene shaken and filtered should show not more than 0.04 gram increase on the filter.)

Coke Residue.—The residue on coking should be not greater than 3 per cent. A high content of asphaltum or free-carbon will give considerable trouble by coking in the cylinders.

Free-Carbon Content.—There should be not more than a trace of free carbon in the oil, as free carbon tends to clog the valves and to deposit on the surfaces of the cylinders.

Volatility.—At least 80 per cent. of the oil should distil over at 350° C., for oil leaving more than 20 per cent. residue at this temperature will show a large carbon content by coking.

Distillation.—Heavy oils and residues, though they may be successfully burned in a heavy-oil engine, should properly be distilled (not refined) before using, as it is cheaper to prepare the oil before introducing into the engine than it is to dismantle the engine, or a part of it, for cleaning.

Flash Point.—The flash point should be between 60 and 100° C. (closed tester). A small proportion of oil of a low flash point is required to insure ignition.

Ignition Oil.—In general a heavy oil containing no material having a low flash point should be enlivened by the addition of about 2 per cent. of a "gas oil," flash point 60 to 100° C. or less, before being fed into the cylinders.

Specific Gravity.—The specific gravity in itself, although of little significance, should be not greater than 0.920, because when greater the large proportion of heavy

residual material would give trouble in the engine. In general the boiling point or distilling proportion is of more importance.

Calorific Value.—The heating value should be not less than 9,000 calories, and the hydrogen content not less than 10 per cent., as lower values are approaching the value of pure carbon and will give poor combustion.

Sulphur Content.—The sulphur content should be not more than 0.75 per cent., as a greater proportion may attack the cylinder walls and will tend to pit them, making them rough. Brass, zinc, and copper are to be avoided in the surfaces exposed to combustion. Nickel steel seems to be the most resistant material.

Acid and Alkaline Content.—The oil should contain no free ammonia, alkalis, or mineral acids, because of their pitting effect on the surfaces exposed to combustion.

Ash Content.—The oil should contain not more than 0.05 per cent. of non-combustible mineral matter, because such matter tends to hasten carbonization within the cylinders and to prevent proper combustion.

Water Content.—The water content should be not greater than 1 per cent. One per cent. of water reduces the calorific value by 1 per cent. Moreover, to raise the temperature of 1 gram of water from room temperature, say 30°, to 100° C. requires 70 calories, and to evaporate 1 gram of water at 100° C. into steam at 100° C. requires 536 calories. Hence 1 gram of water causes a total reduction of 536 + 70, or 606 calories, and to raise the temperature of the steam to that of the cylinder requires still more heat. The absorption of heat in raising the temperature of the steam is partly compensated by the action of the steam in expanding and performing work on the piston, there being an abundance of heat in the cylinders. In short, 1 per cent. of water in the fuel itself will cause a loss of approximately 1.06 per cent. in the calorific value of the fuel. It must also be remembered that a drop of water suddenly generated into steam within the fuel spray at the instant of ignition may lower its temperature and thereby prevent ignition, and a number of such drops in succession might stop the engine.

Resin Content.—The resin content should be low, as resins have a tendency to carbonize readily and will tend to coke in the cylinders.

Creosote Content.—Oils containing creosotes up to 12 per cent., though causing smoke to some extent, can be burned; a higher percentage of creosote gives trouble by coking.

Paraffin Content.—A paraffin content of 15 per cent. will give some trouble. An oil containing a still higher percentage of paraffin, because of the large quantity of oxygen necessary for complete combustion, will burn with more difficulty.

Asphaltum Content.—The heavy-oil engine, at least so far as the use of asphaltum oils is concerned, is still in its experimental stage, but the assumption can fairly be made that when the mechanical difficulties are surmounted it will be practicable to burn any fuel oil containing asphaltum that is sufficiently fluid to flow, providing the oil be free from solid matter and water. An oil containing 21 per cent. asphaltum has been successfully burned.

Atomization.—Fine atomization is essential, for if the fuel enters the cylinder in drops of appreciable size, which can burn only from their surfaces, it will not have time for complete combustion. The fuel will consequently strike the sides of the cylinders and the piston head and there carbonize.

COAST TO COAST.

Ottawa, Ont.—The report of the Conservation Commission on the Long Sault power development scheme will shortly be ready for submission to the Government. It will declare emphatically against such an undertaking being turned over to any company, and that if the power is harnessed it should be done by the Government. The engineers have found the scheme quite feasible from their standpoint, but there would be danger to navigation as well as risk of flooding adjacent territory. The immense value of the power as a natural resource will be emphasized, together with a declaration that its export from the country should not be permitted. The report is now being revised by Hon. Clifford Sifton, chairman of the Commission.

Ottawa, Ont.—If Canada becomes a base of supply for oil fuel for the British Admiralty in furtherance of its scheme for operating warships by that method, the sands of the Athabaska River will be the principal source, is the opinion of Mr. James Whyte, deputy head of the Conservation Commission. "If the tar sands of the Athabaska mean anything," said Mr. Whyte recently, "it is that below them are quantities of petroleum. On three occasions wells have been sunk, but this was always done on a wrong principle. The boring was not of sufficient size. It is wholly probable that if the examinations were made under proper conditions the supply would be forthcoming in paying quantities. We are endeavoring to interest capitalists in the proper development of these deposits. The oil in the eastern wells is too valuable as an illuminant to be used for fuel."

Montreal, Que.—After careful consideration, the Harbor Commissioners have decided that the projected extensions to the Alexandra, King Edward and Jacques Cartier piers cannot be commenced this season. When the programme of works for this year was given out, it was announced that the Commissioners were desirous of extending each of these piers, but that they would await certain alterations which the Dominion Government intended to make at the entrance of the Lachine Canal before putting the work in hand. After the collision between the lake steamer "Calgary" and the "Levenpool," while the latter was lying at her berth at Shed 15, the Harbor Board reconsidered the question, as the danger to navigation in the harbor of the sterns of ships projecting beyond the piers at which they were berthed was obvious. Finally, the decision has been arrived at that the work cannot be undertaken, pending the alterations referred to above, as the congestion of traffic that would inevitably result would be too great.

Victoria, B.C.—Dr. G. A. B. Hall, medical health officer, and Mr. Birch, the city analyst, discussing Dr. Newnham-Davis, advocacy of the oxychloride process of treating sewerage, remarked that the use of salt water by its electric decomposition had been tried in the East with success. The isolation of chlorine by electrolysis results in the typical disagreeable odor, which would have to be cared for by rendering the gas soluble in water and using it over again. As a disinfectant the results in hospitals and surgeries are well known, and there is no reason why it should not succeed in sewerage treatment. At the present time in the north-west sewer scheme experiments are being made to determine the course of currents so as to ascertain whether the tide would bring back sewerage from McLoughlin Point to the Inner Harbor. If it is necessary to treat the sewerage, as is done in the oxychlorine process, two tanks would be necessary, and it is the intention of the health department to secure some more information on the subject.

Hull, Que.—At a special meeting of the Hull city council, held recently, a motion was passed approving of the Federal

Government project for the embellishment of Hull and Ottawa, and expressing the willingness of the city to pay their share towards paying for the cost of the preparation of the plans, as contained in the report of the special committee appointed by the city council, which interviewed Hon. George Perley. Mayor Dupuis had no written report of the work accomplished by the committee, but submitted a verbal one. He stated that he with Alderman Doucet and Alderman Thibault interviewed Hon. George Perley, and were advised that plans of the Federal Government's project had been prepared and would be submitted to the cities of Ottawa and Hull, who would be asked to pay half the cost of their preparation pro rata according to the population That the said plans might cost in the neighborhood of $50,000, of which sum the Government would pay half, Ottawa would pay $20,000 and Hull $5,000

Vancouver, B.C.—"The engineers of the Provincial Forestry Department who are to cruise the timber in the watersheds of the various creeks on the north shore of Burrard Inlet, will commence their work immediately," stated Alderman Black, chairman of the waterworks committee of the city council. Asked when he expected the reports of the two parties would be available to the waterworks committee, Alderman Black said that he thought it would take the engineers and cruisers about two months to complete their work and prepare their reports. It is expected that when all the information and data that the reports will contain are received and digested the scheme of Alderman Black's for the conservation of the waters of the streams from which Vancouver derives its water supply will be proceeded with. This scheme, which has already been made public, involves the purchasing by the city of timber limits in the watershed of Seymour Creek for a number of miles from the present intake towards its source and the construction of a dam which will create a reservoir lake with sufficient water to meet all demands made upon the source of supply for future years during the dry season.

Ottawa, Ont.—Simultaneous with the appointment of the three highway commissioners by the Ontario Government come various opinions and recommendations regarding the good roads movement throughout the province. In the hope of getting suggestions which might be passed on to the new commissioners, the secretary of Ontario good roads has communicated with the reeves of various townships scattered about the province, and the result is a decided tendency to ask more money from the government. The most common recommendation is that the government pay one-half the cost of good roads construction, instead of one-third, as provided under the Highways Act.

A second common demand is that motorists be compelled to pay more towards the roads they help to destroy. Complaints are made that motors wear roads out faster than the townships can afford to keep them repaired, and that it is the motor and not the horse vehicle, which does the bulk of the damage. This seems to be particularly the case in townships lying close to the larger cities. Force motors to pay a high tax, proportionate to weight of the car, is the suggestion.

From one county comes the recommendation that the roads leading from large centers of population, bear the full cost, and hold this out as an incentive to the more remote districts. Some districts are not inclined to favor the movement entirely, stating that more progress will have to be made at less cost, or the system will rapidly become unpopular among the people who are now paying the bills. The government, however, might absorb a good share of that cost.

The suggestion of a frontage tax comes from another country. It is a recognized thing that improved roads increase the value of adjoining farms and the recommendation is that these farmers help pay for the roads in larger percentage than those whose farms are benefitted less.

Quebec, Que.—The Quebec Board of Trade has forwarded a memorial to the Minister of Public Works advocating the establishment of a modern steel shipbuilding plant at Levis in connection with the new drydock that is to be built by Messrs. M. P. and J. T. Davis. The memorial points out that in order to ensure the proper working of the dock it will be necessary to maintain a staff of competent shipbuilders and ship repairers and that these men must have constant work.

Winnipeg, Man.—Practical assurance has been given to the Winnipeg and St. Boniface Harbor Commission that the Dominion Parliament will appropriate the sum of $100,000 in the next estimates to be brought down for the purpose of improving the harbor facilities on the Red River. Assurances to this effect have been given to the commissioners by Hon. Robert Rogers, Minister of Public Works in the Dominion Government, who has taken a deep interest in the work of the Commission ever since it was formed.

Ottawa, Ont.—Plans are well advanced, and tenders will be called for shortly for the new interior terminal elevators to be erected by the Government at Moose Jaw and Saskatoon. The designs are being made by the Barnet-McQueen Company, under direction of the Grain Commission. The works will go on this autumn, but final steps to build similar elevators in Alberta have not yet been taken. The interior elevators are designed to facilitate the farmers in marketing their wheat and getting their cash, and their establishment has long been urged by the grain grower societies. The Grain Commission intends to add a chemist to its staff for examination and analysis of wheat.

Vancouver, B.C.—Either water consumers of the city must show a less wasteful disposition in the use of water, or the Water Commissioner will be forced to resort to the Elk Lake supply to augment the supply being received from the Esquimalt Waterworks Company's system. With the advent of hot weather the demand for water has jumped by leaps and bounds, until now the supply being daily taken from the mains of the private company is 4,750,000 gallons, and the limit which the city can take under its agreement, and which can be delivered through the temporary main at the pressure given by the company is 5,000,000 gallons. The great superiority of the Goldstream supply, both as to temperature, taste and quality, induced the Water Commissioner to shut down the Elk Lake supply altogther, with a view of improving that source of supply while the water there is at its lowest point. But of late the demand has shown such an increase that this policy had to be discontinued. Water Commissioner Rust stated recently that Elk Lake water at this time of year, from its odor and color, is not desirable, and his idea had been to cut it off altogether, as he did not desire to mix the supply from the two sources. But the useless waste of water during the night has made it imperative to turn Elk Lake water into the main supplying the northwestern section, and in consequence many complaints have been received from that section. He believes that, with the assistance of the consumers, the great waste can be obviated. The 5,000,000 gallon supply, he states, should be more than ample to meet all legitimate demands, but with hundreds of thousands of gallons going to waste every night, the problem of keeping up the supply is a dicult one, especially in the warm weather. If the consumers will assist, the supply will be ample during the day, and the reservoir steadily increased during the night.

Victoria, B.C.—To approve a satisfactory system of dividing the cost of construction and maintenance of the new Johnson Street bridge the city council sat in special session recently. The two draft agreements between the city

and the Esquimalt and Nanaimo Railway on one hand, and the city and the British Columbia Electric Railway on the other were the subjects of discussion, and several changes were suggested to protect the city's interests. For the first time it developed from a remark that the share of the provincial government will be $150,000. This will be given as a lump sum to aid construction, and will involve no obligation to contribute anything towards maintenance, as the government does not regard itself as bound in any sense to assist in the future payments for the bridge. The British Columbia Electric Company's share is to be $50,000. The share of the Canadian Pacific is to be such a sum as would put a new bridge on the present site, which, the engineer said had been set at $80,000. The balance, some $120,000, is to be found by the city. Maintenance is to be met jointly by the three last-named parties to the scheme.

PERSONAL.

CHARLES A. MAGRATH, W. A. McLEAN and A. M. RANKIN have been appointed by the Ontario Government as a commission on Ontario roads.

WM. STORRIE, A.M.I.C.E., until recently waterworks engineeer for the city of Ottawa, has joined the staff of the John M. Ver Mehr Machinery Company, the builders of the Ransome municipal filters.

W. A. CASEY has been appointed municipal engineer at Esquimalt, B.C. Mr. Casey was previously a member of C. H. Topp's staff, Mr. Topp carrying on a consulting engineering practice in Esquimalt.

GEORGE A. JOHNSON, of Johnson & Fuller, consulting engineers and sanitary experts, of New York city, was a visitor at the offices of *The Canadian Engineer* while passing through Toronto last week.

SIR ALEXANDER H. BINNIE, of London, Eng., has been obliged to relinquish his appointment with the city of Ottawa to report on water supply, owing to ill-health. Messrs. William Binnie and R. S. Tickell have been appointed to do the work.

E. P. A. PHILLIPS, B.A.Sc., O.L.S., has been appointed corporation surveyor for the city of Port Arthur. Mr. Phillips is a graduate in civil engineering of the University of Toronto, and has for some time been engaged in surveying with the firm of J. G. Mackay, of Hamilton, previous to which he was a member of the firm of Pierce & Phillips, Porcupine, Ont.

J. B. CHALLIS, B.A.Sc., superintendent of the Dominion water powers branch, and S. J. ROBINS, assistant private secretary to the Minister of the Interior, have left for the coast for the purpose of consulting with the British Columbia Government with regard to water powers in the railway belt there.

M. J. PATON, M.A., has resigned his position as assistant secretary and editor for the Conservation Commission to accept the position of treasurer of the Publishers' Association of Canada, with head offices in Toronto. He is an honor graduate of Queen's University, having obtained his M.A. in 1909 and winning the gold medal in economic science.

LAWFORD GRANT, who recently resigned the managing-directorship of the Canadian British Insulated Company, Limited, Montreal, will assume his new position with the Eugene Phillips Electrical Works, Montreal, in about a week. Mr. Grant retains the presidency of the Canadian British Insulated Company. He is succeeded in the managing-directorship by his brother, A. E. Grant, formerly manager of the Cardiff office of British Insulated and Helsby Cables, Limited.

OBITUARY.

DAVID BURNS, lecturer on higher mathematics and structural drawing at the Carnegie Institute of Technology, Pittsburg, died at his home in that city on July 27th. Deceased was born and educated in Toronto, being one of the early graduates of the School of Practical Science, receiving the degrees of civil engineer and Ontario and Dominion land surveyor. He had considerable railway and bridge construction experience, holding positions with the Pennsylvania Railroad, the Keystone Bridge Works and the American Bridge Company. He has been connected with the Carnegie Institute since 1904.

COMING MEETINGS.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—The Twelfth Annual Meeting to be held in Canada during July and August. Opening day of the Toronto Session, Thursday, August 7th. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ONTARIO MUNICIPAL ASSOCIATION.—Annual Meeting to be held in Toronto, August 28th and 29th. Secretary-treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Annual Meeting in Regina, September 16th, 17th and 18th. General Secretary, Major Drum, Ottawa; Local Secretary, Dr. Murray, Regina.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington,

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, Lo21 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

AMERICAN CONCRETE INSTITUTE.—First Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

Concrete work in the Panama Canal locks is nearly completed, the aggregate amount in place at the close of work on June 21st, being 4,471,463 cubic yards.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for smal fee.

19798—July 16—Authorizing Government of Saskatchewan to construct Third Street East across C.N.R., at Service Townsite, in S.W. ¼ Sec. 26-8-1, W. 2 M., Sask.

19799—July 11—Approving British America Express Co.'s Standard Tariff, C.R.C. No. 12, filed in compliance with General Order No. 104.

19800—July 17—Amending Order No. 16998, dated July 13, 1912, to provide that Charlemagne St., Maisonneuve, be left open; and that application with respect to streets to the east be refused.

19801—July 17—Authorizing C.N.O.R. to construct across public road between Lots 13 and 14, Con. 1, Tp. Pembroke, by means of a structure carrying railway over highway: Provided a proper road be left for John A. Gourlay, owner of part of Lot 14, Con. 1, between road shown on plan, being at right angles to road to be crossed, and Muskrat River.

19802—July 17—Approving revised location C.N.O.R., through unsurveyed territory, Dist. Algoma, Ont., mileages 198.26 to 201.66.

19803—July 17—Authorizing Mun. Tp. South Hull, Que., at its own expense, to construct crossing over C.P.R., mileage 9.7, from Aylmer, on Waltham Subdivision, of said railway, where it intersects road now being built to join present Eardly Road.

19804—July 17—Authorizing C.P.R. to construct, by means of grade crossings, additional track across fifteen (15) highways, mileages 1.00 to 15.38, Moose Jaw Subdivisioo, Saskatchewan Division, Sask., mileage o being at Broadview.

19805—July 17—Approving revised location C.P.R. main line, as constructed, from mileage 74.46, a point in Sec. 20-28-25, W. 5 M., thence to a point in Sec. 34-26-26, W. 5 M., mileage 88.56, Mountain Subdivision, B.C.

19806—July 11—Authorizing G.T.P. Ry. to construct spur across C.N.R. between Edmonton Portland Cement Co.'s spur and Can. Nor. Alta. Ry. in N.E. ¼ Sec. 6-53-19, W. 5 M., Dist. North Alta., Alta.: Crossing be protected by a diamond inserted in track of C.N.R., and by watchmen; such crossing to be temporary until such time as C.N.R. commence to operate its line at point in question, when this Order shall be rescinded. Cost of inserting and maintaining diamond and cost of watchmen at said crossing to be borne and paid by G.T.P. Ry.

19807—July 17—Authorizing G.T.P. Ry. to construct spur for the Edmonton-Portland Cement Co., Limited, in Sec. 1-53-19, W. 5 M., Alta.; spur to be completed within three months from date of Order.

19808—July 15—Approving G.T.R. plan showing proposed automatic block installation on Victoria Jubilee Bridge, Montreal, carrying automatic block district from east end of Point St. Charles across bridge to St. Lambert and connecting it with the interlocking plant at St. Lambert Junction.

19809—July 17—Authorizing C.P.R. to construct spur for Messrs. Watson and Todd, Limited, Ottawa, Ontario.

19810—July 18—Extending until September 15th, 1913, time within which G.T.P. Ry. install interlocking plant at crossing of C.N.R. by G.T.P. stock yards spur, St. Boniface, Man., as required by Order No. 16930, dated June 29th, 1912.

19811—July 18—Extending until September 15th, 1913, time within which interlocking plant be installed at crossing of Fort William and Port Arthur St. Railway, by G.T.P. Ry. Lake Superior Branch at Syndicate Avenue, Fort William, Ontario, as required by Order No. 17657, dated September 24th, 1912.

19812—July 18—Authorizing C.P.R. to reconstruct bridge No. 18.1, near Inglewood Station, Tp. Chinguacousy, Ont., Div. Orangeville Subdivision.

19813—July 17—Authorizing C.N.R. to extend existing spur for Twin City Coal Company, Limited, across Sixth Street East, Edmonton, Alta.

19814—July 17—Approving location C.P.R. Port Moody and North Shore Branch, from a point at end of Port Moody Branch, Station 182.70, to ferry dock, east side of North Arm; and from Roche Point, where car ferry is shown on plan, to Hendrie Avenue, Province of British Columbia.

19815—July 17—Authorizing city of Regina, Sask., to construct its Municipal Street Railway, across Arcola Branch of C.P.R., and the Commercial Spur of said company, where said tracks cross Winnipeg Street, between Ninth and Tenth Avenues, at rail level, city of Regina, subject to and upon certain conditions.

19816—July 18—Authorizing Hamilton Street Railway to construct across spur belonging to Oliver Chilled Plow Works of Canada, Limited, (operated by G.T.R. and T.H. & B. Railway Companies) on Gilkison St., opposite McKinstry Street, city of Hamilton, Ont., subject to and upon certain conditions.

19817—July 17—Approving location G.T.P. Branch Lines Company's stations, namely:—Erith, 23-51-19, W. 5 M., mileage 10.7; Weald, 7-51-19, W. 5 M. 16.4; McLetod River, 7-52-18, W. 5 M., M. 5.5; Embarras, 8-50-20, W. 5 M. M. 25.2 and Minchead 10-49-21, W. 5 M. mileage 34.0 Province of Alberta.

19818—July 18—Approving station site and station of G.T.P. Branch Lines Company at Charlton, Bear's Head and The Lean Man Indian Reserves, Nos. 110 and 11, Battleford Branch, Saskatchewan.

19819—July 18—Approving locatioo Algoma Eastern Railway Company, station at town of Little Current, Dist. Manitoulin, Ontario.

19820—July 17—Approving location G.T.P. Ry. stations in Ontario, namely:—Petry, mileage 114, Dist. Thunder Bay; Empire Ave., Lot 8, Con. 2, Neebing Tp. Fort William, mileage 0.7; Kelly, mileage 75.12, Dist. Thunder Bay; Yonde, mileage 170.16, Dist. Kenora and Alcona, mileage 184.8, Dist. Kenora.

19821—July 17—Approving location C.P.R. stations on Weyburn Westerly Branch, Sask., namely:— Verwood, S.E. ¼, 31-6-27, W. 2 M.; Mayroone, L.S. 13, 24-8-7, W. 3 M.; Aneroid, S.E. ¼, 9-9-10, W. 3 M.; Kincaid, N. ½ N.E. ¼, 22-8-8, W. 3 M.; Landscape, N.E. ¼, 13-6-27, W. 2 M. and Hazenmore, S.E. ¼, 34-8-9, W. 3 M.

19822—July 18—Directing G.T.R. to construct at its own expense, a crossing over its railway between Lots 5 and 6, Con. 7, Tp. Fitzroy, mileage 160, near Carp, Ont., easterly line of proposed road over Ry. Co.'s property to be 60 ft. clear of westerly end of culvert.

19823—July 17—Authorizing N. St. C. and T. Ry. subject to terms and conditions contained in resolution of town of Niagara, dated March 19th, 1913, to construct spur along King and John Streets, town of Niagara-on-the-Lake, from points "A" to "B", to connect lines and tracks of said spur with Michigan Central R.R. siding from points "C" to "D" and "E" to "F"; and cross Regent Street said town, spur to be completed within three months from date of this Order.

19824—July 11—Granting leave to city of Medicine Hat, Alta., to construct subway on Esplanade Street, city of Medicine Hat, work to be completed within six months from date of this Order, etc.

19825—July 11—Approving revised location portions of C.P.R. main line as constructed from mileage 18.27, a point on West Boundary, N.W. ¼, Sec. 12-10-22, W. P M., in westerly direction to a point on easterly limit of S.E. ¼, Sec. 30-9-24, W. P M., mileage 35.69 and from M. 115, N.W. ¼, 4-16-2, W. 2 M. to N.W. ¼, 19-16-3, W. 2 M., mileage 124, (zero of mileage being at Brandon, Man.); 2, authorizing construction of additional track across 26 highways, mileage 19.45 to 122.92; 3, divert road in Sec. 27-9-23, W. P M. and 4, after diversion Co. close portion of road allowance between Secs. 22 and 27-9-23, W. P M., within its right of way.

19826—July 18—Authorizing C.P.R. to operate bridge No. 109.7, over Pitt River, Cascade Subdivision, B.C., provided operation of trains over bridge be limited to a speed not exceeding six miles an hour.

19827—July 11—Authorizing C.P.R. to construct road diversion in Sec. 33-14-9, W. 4 M., at Suffield, on Suffield-Blackie Branch, after diversion Co. may close portion of preseot road allowance between Secs. 32 and 33-14-9, W. 4 M within its, right of way.

19828—July 11—Authorizing C.P.R. to construct branch line for S. E. Stewart, Saskatoon, Sask.

19829—July 18—Authorizing C.P.R. to construct proposed double track of main line as already constructed, across Municipal Roads D.G.S. 66 and 67, D.G.S. 86 and 87 and D.G.S. 93, Parish Kildonan, Manitoba.

19830—July 14—Directing that all switching movements on the two sidings (G.T.R.) which parallel the main line, be flagged over crossing of Barrett Street, town of Port Hope, Ontario.

19831—July 14—Amending Order No. 19239, dated May 9th, 1913, by adding words, 'between the hours of 8 a.m. an d8 p.m., and that all movements over the crossing between 8 p.m. and 8 a.m. be flagged over by one of the train crew,' after word 'Flagman,' in second line of operative part of Order.

19832—July 18—Authorizing Department of Public Works, Alta., at its own expense, to construct highway crossings over G.T.P.R. Calgary Branch, in N.E. ¼, Sec. 27-45-21, W. 4 M. and S.E. ¼, 34-45-21, W. 4 M., at Duhamel, Alta., applicant, at own expense and cost, do all grading required for approaches to said crossings and thereafter maintain same; Ry. Co at sole cost of applicant, provide all material, including crossing planks, suitable and proper cattle guards, crossing signboards and turned in fences and all work to conform with Railway Act. All questions as to protection of said crossings is reserved for further consideration.

19833—July 14—Authorizing city of Saskatoon, Sask., to construct highway across C.N.R. at Hilliard Street, Saskatoon.

19834—July 11—Substituting C.N.O.R. plan "A." dated Toronto, June 20th, 1913, showing proposed crossing over Conklin River, for plan approved under Order No. 18598, dated Jan. 29th, 1913.

19835—July 17—Authorizing C.N.R. to construct "Wye" through southeast ¼ sec. 28-55-25, W. 4 M., Alberta; to be completed within three months from date of this Order.

19836—July 18—Directing C.P.R. to install improved type of automatic electric bell at crossing known as "Muler Crossing," about ¾ of a mile west of Kingsbury, P.Q., and thereafter maintain bell at its own expense; 20 per cent. of cost of installing bell to be paid out of the Railway Grade-Crossing Fund, and remainder by railway company.

19837—July 18—Directing (1) that C.P.R. cut down 4 or 5 feet of earth on west side of crossing of river road about three miles east of Kingsbury, between Melbourne and Windsor Mills, on top of the rock, and raise west approach, so that approaching trains may be seen 900 feet away at a distance of 100 feet from the crossing; (2) within 60 days from date of this Order railway company install improved type of automatic electric bell at said crossing, and thereafter maintain bell at its own expense; 20 per cent. of cost of installing bell be paid out of the Railway Grade-Crossing Fund, and remainder by railway company.

19838—July 10—Directing that C.P.R. repair retaining wall, raise it at least one foot higher, and erect standard railing along same; widen road on south shore of St. Francois River, running parallel to C.P.R. (Orford Sub.-Div.) at mileage 55, to width of at least 18 ft. throughout, without disturbing too much of permanent slope of hillside, and put in retaining wall to hold up toe of slope.

(Continued on page 84.)

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

▲—Denotes an item regarding work advertised in *The Canadian Engineer.*
+—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

RAILWAYS—STEAM AND ELECTRIC

Montreal, Que.—Word comes from London that the $4,000,000 4½ terminal debenture stock of the Canadian Northern Pacific has been fully subscribed before the advertised time of its closing. The scrip was quoted at a quarter premium.

+—Ottawa, Ont.—The Dominion Government has awarded the ROGER-MILLER COMPANY, Toronto, the contract for the Prince Edward Island terminal at Carleton Point, of the Intercolonial Car Ferry. The contract price is $950,000 which is the lowest.

Ottawa, Ont.—Tenders will be received up till the 14th of August, 1913, for supplying 41,000 track ties. Plans and specifications may be obtained from the Department of Railways and Canals. L. K. Jones, Secretary.

Toronto, Ont.—An army of twenty-five thousand men are now at work on the steel which will bind British Columbia and the western provinces with the Atlantic outlets on the east when the Canadian Northern Transcontinental line is completed next spring. Of this number nine thousand are working on the line east of Port Arthur and sixteen thousand on the line in Western Canada. Reports up to the beginning of the month on the construction of the connecting line in Eastern Canada show 117 miles of steel from Port Arthur east, 34 miles west from Oba, 12 miles east from Oba, 82 miles west from Ruel now completed. Work on the portion of the Transcontinental between Yellowhead Pass and Port Mann, B.C., is now more than 80 per cent. accomplished, and unless some of the bridges take longer to build than is anticipated, the whole line to the Pacific coast should see completion this coming winter.

Victoria, B.C.—Although the oil-burning locomotives have been in use on the E. & N. Railroad for a comparatively short period, they already are providing a distinct improvement over the coal burners. While the change has involved a considerable initial expenditure, the chief item of which is in connection with the construction of oil tanks, it is apparent that the innovation effects a saving in several respects, the importance of which will be more strikingly evident at a later date. For one thing, the necessity of patrolling the right-of-way, has, to a large extent, been obviated. Besides the forest fires, which in previous summers have caused serious destruction along the line, have not been experienced thus far. This is directly attributable to the use of oil.

BRIDGES, ROADS AND PAVEMENTS.

+—Bassano, Alta.—The Government has awarded Capt. McKINNERY the contract for the erection of the new bridge across the Bow River.

+—Burlington, Ia.—The DOLARWAY PAVING COMPANY have been awarded the contract for the construction of 7,700 square yards of pavement. The contract price is $1.45 per square yard.

Calgary, Alta.—The City Council have decided to cancel a large number of contracts for sidewalks, on the ground that they were projected out into the suburbs so far that there are no people to use them. It has been decided that in future sidewalks will not be built until they are needed. Approximately $30,000 worth of contracts have been cancelled in Sunnyside subdivision alone. As well, many contracts have been cancelled in other parts of the city.

▲—Cayuga, Ont.—Tenders will be received up till the 16th of September, 1913, for the construction of 26½ miles of stone macadam road. Plans and specifications may be obtained from Messrs. Jackson and Kyd, county engineers, and T. A. Snider, county clerk.

+—Fort George, B.C.—The G.T.P. has awarded the BATES-ROGERS CONSTRUCTION COMPANY, Chicago, the contract for the construction of a bridge across the Fraser here.

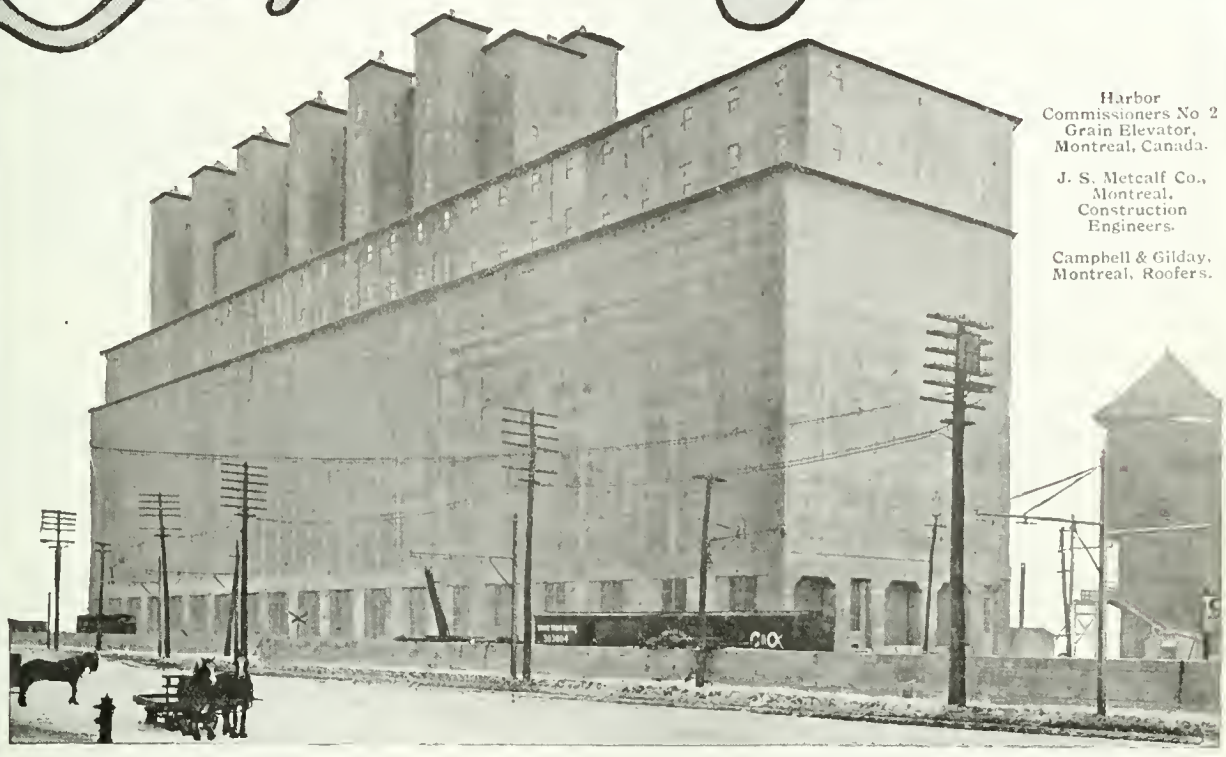
Halifax, N.S.—Tenders will be received up till the 11th of August, 1913, for the erection of bridges and culverts in Inverness County. Plans and specifications may be obtained from the Department of Public Works and Mines, Halifax. E. H. Armstrong, Commissioner.

London, Ont.—The Board of Works has awarded the contract for the abutments and approaches of the West London bridge to Messrs. BAIN & ROSS, of Embro, for the sum of $6,441. Two other tenders were received, one from Freeman Talbot for a solid concrete foundation, instead of reinforced concrete, as the accepted tender demanded, for the sum of $9,900, and from Frank Barber for the sum of $8,845. The superstructure will be tendered for later.

Montreal, Que.—City Engineer Janin in a report to the Board of Control announced that no tenders had been received for the construction of cement sidewalks on nearly one hundred street sections.

+—Natrona, Pa.—The DOLARWAY PAVING COMPANY have been awarded the contract for the construction of 5,900 square yards of pavement. The contract price is $1.38 per square yard.

Barrett Specification Roofs



Harbor Commissioners No 2 Grain Elevator, Montreal, Canada.

J. S. Metcalf Co., Montreal, Construction Engineers.

Campbell & Gilday, Montreal, Roofers.

On the World's Largest Concrete Grain Elevator

As we have frequently pointed out, most of the large commercial buildings of the day are covered with a Barrett Specification type of roof.

For example, here is the great new grain elevator at Montreal. It is said to be the largest in the world, with a capacity of 2,600,000 bushels. It carries a Barrett Specification Roof 55,000 square feet in area.

The engineers chose this type of roof because it is the lowest-priced and most reliable roofing known.

Barrett Specification Roofs require no repairs or attention of any kind, they invariably last twenty years or more, and are fire-retardant.

Architects, engineers and owners of permanent buildings of all kinds should have a copy of the Barrett Specification on file.

A request will bring it by return mail.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification revised August 15th, 1911, using the materials specified and subject to the inspection requirement.

THE PATERSON MANUFACTURING COMPANY, LIMITED

Montreal Toronto Winnipeg Vancouver St. John, N.B. Halifax, N.S. Sydney, N.S.

+—**North Vancouver, B.C.**—The District Council recommended that Messrs. WAUGH, WISNER & BAILEY be given the contract for filling in McCartney Creek. The contract price is $24,320. The next lowest tender was that of Mr. T. R. Nickson for $25,515.

Peterborough, Ont.—City Engineer Parsons will call for tenders for the construction of pavements on several streets, shortly.

+—**Regina, Sask.**—The city council has awarded the CANADIAN WESTRUMITE COMPANY the contract for the construction of 500 square yards of pavement. Their tender was $33 higher than that of the National Pavers, who were recommended by the city engineer, but as the former had all the materials on hand and could go ahead with the work at once the commissioners recommended that the pavement be laid by the Westrumite people. Their tender price for the whole work, including pavement, curb and gutter work, is $1,749.

+—**Rossland, B.C.**—The West Kootenay Power and Light Company has awarded the CANADIAN GENERAL ELECTRIC COMPANY the contract for supplying a 75,00 K.V. water-wheel driven generator. The CANADIAN ALLIS-CHALMERS, LIMITED, will supply the water-wheel. It will have a capacity of 9,000 horse-power at 180 r.p.m. under a head of 70 feet.

+—**Saskatoon, Sask.**—The city has awarded Messrs. McKENZIE & THAYER the contract for supplying 20,000 tons of coal for power production. The contract price is $168,000.

+—**Saskatoon, Sask.**—The Provincial Government has awarded R. J. LECKY AND COMPANY, Regina, the contract for the construction of a new traffic bridge across the river. The contract price is $398,000 which is $98,000 above the amount agreed by the city and the government and in all probability another by-law will have to be submitted to the people to take care of the thirty-three thousand odd which was not reckoned in the amount first submitted to the p
next lowest tender was that of T. J. Robertson, amounting to $604,000 and the third tender showed the largest range of all, being for $837,000 from Parson Bros., also of Regina.

+—**South Vancouver, B.C.**—The Council has awarded the DOMINION CREOSOTING COMPANY the contract for creosoted wood blocks on Main and Fraser Streets. The cost is $750,000.

Toronto, Ont.—Owing to the opposition of a large number of ratepayers, the proposed construction of a three-year temporary pavement on Yonge Street at a cost of $127,000 has been abandoned and the present road will be temporarily repaired at a cost of $30,000 as originally intended at the expense of the ratepayer at large.

+—**Vancouver, B.C.**—The Board of Works have recommended that the following pavement contracts amounting to $220,000 be awarded:—Main Street, Eighteenth to Twenty-fifth Avenues, M. P. COTTON COMPANY, LIMITED, $23,-100; South Cambie Street, from Dufferin to Broadway, COLUMBIA BITULITHIC COMPANY, $29,643; Heather Street, from Broadway to Twelfth Avenue, B. C. GRANITOID COMPANY, LIMITED, $12,061; Heather Street, Twelfth to sixteenth Avenues, COLUMBIA BITULITHIC COMPANY, $14,139; Vernon Street, from Harris to Venables Streets, M. P. COTTON COMPANY, $6,700; Water Street, from Cambie to Carrall Streets, COLUMBIA BITULITHIC COMPANY, $23,500 and Hastings Street from Victoria Drive to Nanaimo Street. Messrs. LEDINGHAM & COOPER, $44,000 and from Nanaimo to Renfrew Streets, Messrs. T. R. NICKSON & COMPANY, $68,500, the two latter on the understanding that the track allowance only would be done this year.

Vancouver, B.C.—The City Council have passed local improvement by-laws in connection with pavements amounting to $1,151,560.

Vancouver, B.C.—The city council have accepted an offer from a London firm for an issue of $2,500,000. This means that one-half of the by-law amount passed in January will be disposed of and many delayed projects will be carried on, chief in importance being the construction of pavements. This work will cost $350,000.

Victoria, B.C.—Tenders will be received up till the 12th of August, 1913, for the construction of bitulithic pavement on a concrete base on the roads of Saanich. Plans and specifications may be obtained from J. R. Carmichael, clerk of the municipal council.

Winnipeg, Man.—Tenders will be received up till the 14th of August, 1913, for the construction of pavement of highway bridge, St. Andrews, Dam. Plans and specifications may be obtained from W. Z. Earle, District Engineer, Winnipeg and the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

LIGHT, HEAT AND POWER.

Fort William, Ont.—Fort William, which claims the distinction of being the largest city on the continent which has not gas for domestic purposes, is going to offset one of its greatest disadvantages to householders by reducing the cost of electricity for cooking and heating purposes, if the City Council hearkens to the appeals of the Board of Trade and the utilities committee of the Council. At its next meeting the Council will consider a resolution from the utilites committee, advising that the present rate for electricity be cut from 3 cents to 1½ cents a kilowatt hour, where it is used for cooking. Under a long-term agreement the city purchases from the company all the electricity that is used for lighting and domestic purposes, and retails it to the consumer.

Montreal, Que.—Tenders will be received up till the 15th of August, 1913, for the construction of a system of underground conduits, main and service manholes, transformer chambers, etc. Plans and specifications may be obtained from the Board of City Commissioners. L. N. Senecal, Secretary.

▲—**Peterborough, Ont.**—Tenders will be received up till the 20th of August, 1913, for the construction of bitulithic and asphalt concrete pavements. Plans and specifications may be obtained from R. H. Parsons, City Engineer.

▲—**Peterborough, Ont.**—Tenders will be received up till the 20th of August, 1913, for the construction of a reinforced concrete arch bridge. Plans and specifications may be obtained from R. H. Parsons, City Engineer.

Prince Albert, Sask.—At a special session of the city council this afternoon it was resolved to suspend operations on the La Colle Falls dam, owing to the available funds for the purpose being expended. Excavation for the spillway and tailrace will be continued. Other city work will be continued and no reductions in the city staff is contemplated.

+—**Toronto, Ont.**—The city has awarded ED. BENNIS & COMPANY, LIMITED, Little Hulton, Bolton, through G. H. Tod, Toronto, the Canadian representative of the firm, the contract for supplying 3 chain grate stokers.

Toronto, Ont.—The Hydro-Electric Commission have decided to enlarge the power station at Niagara Falls and to double the line between Dundas and the Falls. This will give the Commission the equipment to double the lines between London and Dundas. The towers are already built and the stringing of the double line to supply the western portion of Ontario with Niagara power, will be commenced at once. It is anticipated that the work contemplated will cost not less than $300,000. The decision of the Commission to double the capacity of the transmission lines from the Falls does not commend itself as an indication that the Commission favor the proposition of Sir William Mackenzie of Toronto to take over the Toronto Electric Light, as a contingency to the purchase of the street railway.

GARBAGE, SEWAGE AND WATER.

Montreal, Que.—The matter of the filtration plant contract will not be settled for some little time. Controller Godfrey said that they wish Mr. McLeod, the contractor, to withdraw his protest to make good the damage by frost to show a satisfactory method of protecting the works from freezing in the winter and state what is the earliest time in which he can finish it. Messrs. Henry and Fuller, New York experts, have gone over the ground carefully and the Board of Control is being guided by their advice.

West Vancouver, B.C.—The council will submit a by-law to the ratepayers shortly asking authorization to raise $100,000 by the sale of debentures for a waterworks system.

+—**Moose Jaw, Sask.**—The City Council has awarded the McMANUS CONSTRUCTION COMPANY the contract for

48 in. CONTINUOUS STAVE LINE.

Manufacturer of

Galvanized Wire Machine Banded

Factory : 1551 Granville Street, VANCOUVER, B.C. P.O. Box 365.

MANNESMANN STEEL TUBES

Seamless or lapwelded—for waterworks, sewage, hydro-electric and gas mains, well boring, boilers and superheaters

SIX HUNDRED AUTHORITIES in Canada and Great Britain are using Mannesmann tubes for water supply systems—in Great Britain in varying quantities up to fifteen miles, in Canada to seventeen miles. Seven hundred miles of weldless steel spigot and faucet tubes—quite apart from flanged tubes and lapwelded spigot and faucet tubes—are in use in the United Kingdom, as well as large quantities in Canada, Australia, South Africa, South America, India, China, New Zealand, and Europe.

Solid drawn tubes are used in places where it is impossible to use cast iron pipe or lapwelded tubes, as well as in places where conditions are more normal. We are constantly adding new customers to our list, and what is of even greater significance, more frequently still receiving repeat orders. In the last five years the sale of Mannesmann welded spigot and faucet tubes increased one thousand per cent.

The saving in joints and the speed with which the mains can be laid makes the total cost of the Mannesmann tubes, when laid, very low. The Mannesmann tubes can be supplied in lengths up to forty feet, and the actual saving by the reduction of from sixty to seventy per cent. in joints, jointing material and labour, is enhanced by the increased safety derived from their being proportionately fewer points of leakage.

Our catalogues treat of the merits of steel pipe versus cast iron and other materials, and show installations of Mannesmann tubes. We can guarantee prompt delivery on all orders and will pay careful attention to any inquiries. Write for booklets.

FIVE STRONG POINTS

1. Our tubes can be bent cold on the spot without trouble.

2. Our tubes can be supplied in lengths up to forty feet, thus effecting a large saving in joints, jointing material and labor.

3. Leakage is reduced to a minimum, as the joints are far tighter and seventy per cent. fewer.

4. Saving in freight, etc., is considerable as a steel tube weighs one third to one-half as much as a cast iron pipe of the same length.

5. Mannesmann steel pipe is covered with a special preparation which acts as a non-conductor, thus preventing any damage to gas or water mains by electrolysis or by extreme variations of temperature. It is impervious to rust in any kind of soil. The outside is covered with special jute cloth. And there are other convincing reasons and illustrations in our booklets.

MANNESMANN TUBE COMPANY, Limited

BOOKLETS ON REQUEST **51 VICTORIA SQUARE, MONTREAL** *BOOKLETS ON REQUEST*

the construction of the high pressure mains system through the business section of the city.

▲—**Toronto, Ont.**—Tenders will be received up till the 19th of August, 1913, for the construction of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, Mayor.

INDUSTRIAL WORKS.

+—**Chatham, Ont.**—The Township Council of Dover has awarded the CHATHAM DREDGING COMPANY, Chatham, the contract for the construction of a cut about 13 miles long and varying in width from 30 to 60 feet, across the township. The estimated cost is $80,000.

Cobalt, Ont.—The Crown Reserve Mining Company and the Kerr Lake Mining Company will undertake to drain Kerr Lake. The pumps used in the draining will be of the semi-dredging centrifugal type, and they will be pumping against a head of no less than 175 feet, a task seldom before attempted with pumps of this type. Some idea of the magnitude of the task may be gathered from the fact that at least three months of constant action by the pumps, leaving mishaps out of consideration, will be required before the lake basin is dry. All arrangements are expected to be completed by August 20th and 31st, and it will thus be almost winter before the water will be lowered sufficiently to allow of any extensive development on the new upper levels.

+—**Edmonton, Alta.**—The Wabamun Power and Coal Company has awarded Mr. H. F. BRACKENRIDGE the contract for carrying out work in connection with the cutting of the first 1,000 feet of tunnel at its mine, located one half mile north of the Grand Trunk Pacific tracks.

+—**Galt, Ont.**—The contract for the construction of the new cement dam across the Grand River has been awarded to THOMAS & HANCOCK. The new structure will be 280 feet long and 10 feet high. It will be located about 35 feet down stream from the present dam, and erected in a straight line across the river.

+—**Montreal, Que.**—The Dominion Government has awarded the DOMINION BRIDGE COMPANY, LIMITED, the contract for supplying the steel work for a freight shed to be built on the Lachine Canal. The contract price is $11,750.

Ottawa, Ont.—Tenders will be received up till the 11th of August, 1913, for the construction of a stone and iron fence to Rideau Hall grounds. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Ottawa, Ont.—The Railway Commission has given judgment approving of the plans and profiles for the new Toronto viaduct which were agreed on by the city railway companies and Toronto Harbor Commissioners, after prolonged negotiations. This practically settles the question of grade separation in connection with the viaduct. Work must be completed by July 29, 1916.

+—**Pitt River, B.C.**—The Dominion Government has awarded the PACIFIC DREDGING COMPANY the contract for dredging. The contract price is $158,220.

+—**Port Burwell, Ont.**—The Dominion Government has awarded the C. S. BOONE DREDGING & CONSTRUCTION COMPANY, LIMITED, Toronto, the contract for dredging required here.

Poupore, Que.—Tenders will be received up till the 2nd of September for the construction of a training pier and revetment wall. Plans and specifications may be obtained from J. L. Michaud, District Engineer, Montreal, J. G. Sing, District Engineer, Toronto and the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

+—**Steveston, B.C.**—The Dominion Government has awarded Messrs. BROLEY & MARTIN, New Westminster, the contract for the completion of a jetty. The contract price is $83,500.

Swift Current, Sask.—The Swift Current Construction Company, a subsidiary of the Western Construction Company, of Reno, Nev., will erect a plant in Swift Current for the manufacture of concrete brick, tile, sewer pipe, trimmings and concrete products. D. Y. Leslie, Board of Trade, Swift Current, is interested.

▲—**Toronto, Ont.**—Tenders will be received up till the 2nd of September, 1913, for the construction of the east pier, eastern entrance, Toronto harbor. Plans and specifications may be obtained from J. G. Sing, Toronto; H. J. Lamb, District Engineer, Windsor, and the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

▲—**Toronto, Ont.**—Tenders will be received up till the 11th of August, 1913, for the construction of two breakwaters. Plans and specifications may be obtained from Frank Barber. County Engineer.

Toronto, Ont.—Engineer Powell and Dr. Nasmith are investigating various proposed methods for abolishing the smell from the sewage disposal works. At present the solid matter is being conveyed to Ashbridge's Bay and covered with clean earth, but this is not entirely effective. A method under consideration is the English filter system, by which the solids are dried, mixed with earth, and made into a fertilizer.

+—**Vancouver, B.C.**—The Dominion Government has awarded Messrs. ARMSTRONG & MORRISON the contract for moving the sections of the Canadian Pacific Railway traffic bridge over the Pitt River, to the government's new traffic bridge.

Victoria, B.C.—The work of dumping rock on the site of the breakwater at Ogden Point is proceeding and the indications are that within the next few weeks the rockbed will be brought to such a level as to permit commencement of the granite blocks. The engineers are concentrating their energies on the first one thousand feet, and this section will be brought to within a few feet of the surface before the next arm of the breakwater is started. By August 14, all the barges, tugs, machinery and other equipment necessary for breakwater construction, that will be needed for the entire contract, will be assembled at Ogden Point. By the middle of the month Engineer McLachlan says that the barges will be dumping 40,000 tons of rock per month at the site of the breakwater.

▲—**Welland, Ont.**—Tenders will be received up till the 25th of August, 1913, for the Port Severn section, Severn Division, Trent Canal. Plans and specifications may be obtained from the engineer in charge, Welland Ship Canal, St. Catharines, Public Works Department, Midland, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Windsor, Ont.—The following by-laws amounting to $15,000, have been passed by the ratepayers. To repair the town dock, $7,000; extending concrete sidewalks, $5,000, and new town hall, $3,000.

MISCELLANEOUS.

Brampton, Ont.—Tenders will be received up till the 18th of August, 1913, for the construction of a clock tower, public building. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—**Bury, Que.**—The Dominion Government has awarded AYTON CROMWELL, Cookshire, the contract for the erection of a drill hall. The contract price is $11,750.

+—**Edmonton, Alta.**—Messrs. Barnes, Cogswell & McCleish have awarded LAURITZEN & RUSSELL the contract or the erection of a warehouse. The contract price is $20,000.

Edmonton, Alta.—The Masons will erect a temple in this city. It will be eight stories in height and cost $500,000.

Edmonton, Alta.—Messrs. Nicholson and Bain will erect a six-story warehouse. The estimated cost is $70,000.

+—**Eganville, Ont.**—The Dominion Government has awarded Mr. L. B. LACHANCE, Ottawa, the contract for the erection of a post-office building.

Kamloops, B.C.—Tenders will be received up till the 16th of August, 1913 for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

+—**Lachine, Que.**—The city has awarded Mr. ADOLPHE GAUTHIER the contract for building an extension to the post-office. The contract price is $20,200.

+—**Moncton, N.B.**—The Maritime Cap Limited, has awarded Messrs. HUMPHREY & DONALD the contract for their new factory building. The contract price is $9,447. Four other tenders were received, that of the Rhodes Curry Company for $17,000 being the highest.

+—**Montreal, Que.**—The Cabinet Council has awarded Mr. JOSEPH BOURQUE the contract for the erection of postal station "F." The contract price is $57,500.

+—Montreal, Que.—The Government has awarded Mr. JOHN QUINLAN the contract for the erection of postal station "L." The contract price is $70,000.

New Westminster, B.C.—Tenders will be received up till the 19th of August, 1913, for the building of an addition to the land registry office. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffiths, Public Works Engineer.

+—North Sydney, N.S.—Mr. FRANK REDDING has been awarded the contract for the erection of the Western Union Cable Office. The contract price is $50,000.

+—Ottawa, Ont.—The Dominion Government has awarded the PIERSON U BAR COMPANY the contract for greenhouses and hot water heating in connection with the experimental farm. The contract price is $19,447.

+—Ottawa, Ont.—The Dominion Government has awarded the FOUNDATION COMPANY, Montreal, the contract for the foundation of the new Customs building.

Port Arthur, Ont.—Tenders will be received up till the 11th of August, 1913, for the erection of a pump-house. Plans and specifications may be obtained from J. J. Hackney, Commissioner of Utilities.

Prince Arthur, Sask.—Tenders will be received up till the 25th of August, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Eugene Fiset, Deputy Minister, Ottawa.

+—Quebec, Que.—The L. H. PETERS COMPANY have been awarded the contract for the construction of the new French Presbyterian church. The contract price is $13,000. The CITADEL BRICK AND PAVING COMPANY were awarded the contract for supplying the brick and stone.

St. John, N.B.—Tenders will be received up till the 11th of August, 1913, for passenger elevator in customs building. Plans and specifications may be obtained from D. H. Waterbury, St. John, and the Department of Public Works, Ottawa R. C. Desrochers, secretary.

Toronto, Ont.—Tenders will be received up till the 12th of August, 1913, for the erection of a market building. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

+—Vancouver, B.C.—Mr. GEO B. BAKER has been awarded the contract for the erection of a warehouse. The contract price is $70,000.

+—Vancouver, B.C.—The John Leckie and Company has awarded Messrs. SNIDER & BRITHAM the contract for the erection of an addition to their present factory. The contract price is $50,000.

+—Victoria, B.C.—Mr. A. LACOURSIERE, Victoria, has been awarded the contract for the erection of the first hotel in Saanich. The contract price is $75,000.

+—Victoria, B.C.—Messrs. Adam Bros. have awarded Messrs. DOW & RYDEN the contract for the erection of a new hotel. The contract price is $45,000.

+—Victoria, B.C.—The Swift Canadian Company has awarded the B. C. GRANITOID COMPANY, Vancouver, the contract for the erection of a reinforced concrete warehouse building. The contract price is $55,000.

+—Winnipeg, Man.—The "Tribune" has awarded Messrs. HAZLETON & WALLIN the contract for additions to the present building. The contract price is $173,000.

Winnipeg, Man.—Tenders will be received up till the 3rd of September for the erection of a drill hall. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

Yorkton, Sask.—Tenders will be received up till the 9th of August for the erection of a telephone exchange building. Plans and specifications may be obtained from D. C. McNab, Deputy Minister of Railways and Telephones.

CURRENT NEWS.

Victoria, B.C.—Mr. Napier Denison, has left for Prince Rupert, Atlin and Dawson, in connection with the meteorological service, intends, if a proper foundation and site can be obtained, to set up one of his very delicate horizontal pendulums, in order that the slow movements known to occur in the Alaska district may be measured daily in the Far North. These results will be of great value when studied in conjunction with the similar work Mr. Denison is carrying on here. This northern station will form one link in the grand chain it is hoped to complete along Western America from the Arctic Circle to the Equator, and eventually it may extend far into South America. The day is rapidly approaching when it may not only be possible to predict the approximate date when the earth's rock mantle will be broken, causing an earthquake, but the probable district in which it may take place. The building now being erected on Gonzales Heights will be the first complete seismological research observatory established in America, which speaks well for the progressive policy of this new country. Not only will the work comprise the constant recording of the earth's very "pulse," but tidal strains in the crust due to the sun, moon and other mysterious forces noted here.

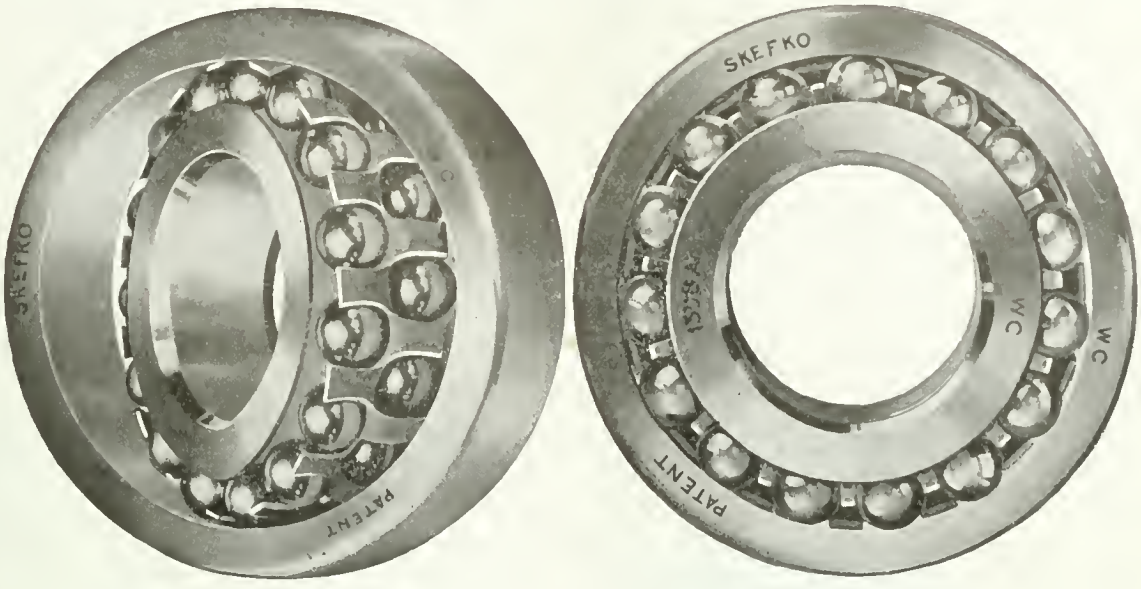
Toronto, Ont.—Ontario will break all records this season in the construction of colonization roads, stated Mr. G. W. Bennett, Provincial Superintendent of Colonization roads recently. The department expects to complete between 1,000 and 1,100 miles of roadway before the end of the year. At the present time over 4,500 men are steadily employed upon the work and some 650 overseers have their hands so full that it is proposed to augment their number by an additional 300. It is also the intention to employ 3,000 more men on cutting out, ditching and grading. All the colonization roadwork this year is being done by day labor. Heretofore a certain percentage has been done under contract, but the day labor work has proved more satisfactory to the government. This year, also, for the first time, Mr. Bennett reports that day labor has been plentiful and excellent. Favorable weather conditions have obtained throughout the north country and the work has progressed with almost remarkable speed. Reasons for the plentiful character of labor the superintendent does not attempt to give. Laborers on colonization roads are paid the regular schedule of wage rates for the locality, and the applications for work have always exceeded the requirements. Moreover, the character of the labor has been much superior to that of other years. There are 20 provincial inspectors, and each of them reported to the department that conditions, labor and construction work were never better than at present. Since the work was taken up in the latter part of April over 800 miles of roadway has been completed. Bit by bit, as the maps in the superintendent's offices show, the unorganized districts of the north are being webbed with good roads. By another season it is hoped that the work of construction will have so far advanced that the government will be in a position to inaugurate its prospective campaign for settlement on a large scale.

MONTREAL MARKET REPORT

Local iron and steel circles are taking some encouragement from the report that matters are improving in the United States. However, up to the present there does not appear to have been any improvement to speak of here. Not long since, Americans were selling pig at $13 Buffalo, being the equivalent of about $17.25, Toronto. It is said that these prices are no longer obtainable. So far as can be learned, the only furnace out of blast is the big 300-ton furnace of the Canada Iron Corporation, at Midland. This will probably not start operations till prices improve. Meantime the corporation has enough orders on hand to keep the 150-ton furnace operating for many months to come. The Dominion Steel Corporation is probably not selling pig-iron save to a few of the local foundries and the Scotia Company is probably not selling any at all. As for the Steel Company of Canada, it is said to be selling at $17,25 Hamilton, which with a freight rate of $2 to Montreal, would make $19.25 here. Other merchant furnaces are all operating on orders but consumption shows a considerable falling off and the trade is not looking for any considerable activity for some weeks to come, at least. In another month buyers will be ordering for delivery before the close of navigation and cargoes of English and Scotch iron will be coming along shortly thereafter. It is claimed that prices on Scotch and English iron are stiffening but little interest is being shown in the market just now, so that it makes little difference what the price across the Atlantic is.

The Snyder-Gillett Contracting Company, of New York State, has been licensed by the Provincial Secretary to do business in Ontario.

No User of Ball Bearings Can Afford to Neglect these Points



1. **Double Row of Balls**—virtually two bearings in one, a splendid feature under any load condition.
2. **Pressed Retainer in One Piece**—made from Swedish Lancashire Iron. No rivets, wires or screws to work loose, jam balls, disarrange spacing or make noise.
3. **Outer Race Spherical**—providing for a frictionless self-alignment that absolutely and automatically compensates for shaft spring.
4. **Best Swedish Crucible Steel**—Carefully heat-treated and uniform in hardness throughout. Unequalled for toughness, carrying capacity, accuracy and durability.

SKEFKO

is the only truly self-aligning bearing. This feature alone is worth most careful consideration ¶ SKEFKO Self-Aligning Double Row, Double-Capacity, Double-Life Ball Bearings cost no more and are made in international standard sizes. Their use is practical under any speed and load condition and the lubrication and protective housing can be made to conform to any service requirements.

¶ SKEFKO Bearings are the recognized standard and are replacing other constructions in many types of machinery.

¶ Our literature explains these matters in detail. Your best interests demand that you investigate. Tell us your bearing troubles and ask for our bulletins.

ST. JOHN QUEBEC MONTREAL OTTAWA TORONTO
WINNIPEG SASKATOON CALGARY VANCOUVER

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

(Continued from page 75.)

work to be done to satisfaction of an engineer of Board, and completed by November 1st, 1913; after construction roadway be maintained by railway company for one year.

19839—July 14—Authorizing Department of Public Works, Ontario, to construct highway across C.P.R. Sault Ste. Marie Branch, on Lot 7, Con. 1, Tp. Drury, Dist. Sudbury, Ont., by means of grade crossing.

19840—July 12—Authorizing C.P.R. to construct bridge No. 2.92, over Toronto Suburban Railway near Meadowvale, Orangeville Sub.-Div., of C.P.R.

19841—July 11—Authorizing C.P.R. to construct spurs for Laurentide Brick and Sand Co., Ltd., across public road and adjoining lands, Co. l'Assomption, parishes of St. Henry de Mascouche and Lachenaie, Que., at mileage 12.25 from St. Martin Jct.

19842—July 18—Authorizing C.L.O. and W. Ry. (C.P.R.) to construct spur across C.N.O.R. in part Lots 24 and 25, Con. A., Tp. Hamilton (West Riding), Co. Northumberland, Ont., at mileage 122.02 on C.N.O. and W. Ry. line, subject to certain conditions.

19843—July 12—Authorizing G.T.P. Branch Lines Co. to construct its Tofield-Calgary Branch across highway in N.E. ¼ sec. 15-44-21, W. 4 M., mileage 43.9, Dist. North Alberta, Alta.

19844—July 21—Approving (1) location G.T.R. Co.'s proposed new station and freight shed to be constructed at New Lowell, Ont., and its proposed rearrangement of track at that point; (2) detail plans of said proposed station and freight shed, filed with Board under file No. 22492.

19845—July 14—Approving location G.T.P. Branch Lines Co.'s station on Battleford Branch, at Dacer, in Sec. 4-43-16, W. 3 M., Sask; station to be in accordance with company's Standard Structural Plan No. 1, on file with Board.

19846—July 14—Authorizing municipal corporation of St. Thomas, Ont., to lay and thereafter maintain 12 inch water main under P.M.R.R. on Wilson Ave., between Ada street and Elm street, St. Thomas.

19847—July 14—Authorizing city of St. Thomas, Ont., to lay 18 inch water main under G.T.R. on Hughes street, St. Thomas, Ont.

19848—July 14—Granting leave to Canadian Copper Co., of town of Copper Cliff, Ont., to construct crossing, with gates, in nature of farm crossing, over Algoma Eastern Ry., in Lot 11, Con. 4, Tp. McKim, at point shown on plan filed under file No. 22501.

19849—May 30—Establishing collection and delivery limits of express companies in city of St. Boniface, Man., and rescinding Order No. 15024, dated Sept. 15th, 1911.

19850—July 18—Directing that, within 60 days from date of this Order, C.N.R. install improved type of illuminated electric bell at crossing of Fort William Road, at a point about half way between Fort William and Port Arthur, and thereafter maintain bell at its own expense, 20 per cent. of cost of installing bell be paid out of the Railway Grade-Crossing Fund; (2) speed of trains operated over said crossing be limited to 6 miles an hour; a signpost be erected at least 250 feet from crossing, indicating that cars must be kept inside that point on spur track.

19851—July 22—Postponing effective date of modification of Rule 7 of G.T.R. Special Freight Tariff, C.R.C. No. E 2374, I.C.C. No. 1660, contained in Supplement Nos. 5 and 3, respectively thereto, and of Rule 33 of C.P.R. Local Freight Tariff, C.R.C. No. E 2141, I.C.C. No. E 1288, contained in Supplement Nos. 9 and 6, respectively thereto, until otherwise ordered by the Board.

19852—July 21—Authorizing C.P.R. to construct road diversion in Sec. 13-13-15, W. 4 M., and construct Suffield-Blackie Branch, by means of grade crossing, across highway between Secs. 12 and 13-15 W. 4 M., at mileage 41.0 from Suffield.

19853—July 19—Authorizing C.P.R. to construct additional track (double track) of main line, Ont. Div. London Sub.-Div., across G.T.R. in W. ½ of Lot 14, Con. 2, Tp. Trafalgar, at mileage 32.56 from Toronto.

19854—July 17—Authorizing C.P.R. to move present farm crossing, on northern section of Atlantic Division of its railway, from its present position at or near mileage 50, north of McAdam Jct., N.B., to a point 190 feet south, on lands of G. Sterling and James A. Peabody.

19855—July 21—Approving and authorizing clearance as shown on plan showing clearance from G.T.R. side track to one of the buildings of Pratt & Letchworth Co., Ltd., Brantford, Ont.; provided G.T.R. (applicant company) keep its men off sides of cars while operating said side track.

19856—July 12—Directing that, in accordance with terms of agreement entered into between John Purvis, predecessor in title of said land, and W. B. Smellie, secretary of railway company, on Oct. 11th, 1887, the Brockville, Westport and North Western Ry. Co. construct cattle pass 8 feet wide and as high as ground will permit, through embankment near or close to the lane leading out from barn on farm of Messrs. D. H. and C. S. Grey, Tp. Elizabethtown, Co. Leeds, Ont.

19857—July 21—Establishing collection and delivery limits of express companies in town of Grand Forks, B.C.

19858—July 22—Disallowing cancellation of stop-over arrangement at Outremont, Que., in connection with shipments of grain and grain products from Western Canada, as contained in Supplement No. 9 to C.P.R. Co.'s "all-rail" and "lake-and-rail" Special Tariff, C.R.C. No. E 2480, said supplement having been made effective June 19th, 1913; (2) suspending, until otherwise ordered by Board, cancellations of stop-over arrangements at Toronto, West Toronto, Montreal and Outremont, in connection with shipments of grain, grain products, hay and potatoes, items Nos. 22 and 23 of C.P.R. Special Freight Tariff, C.R.C. No. E 2141, as contained in Supplement No. 16, effective July 23rd, 1913.

19859—July 21—Authorizing Moose Jaw Electric Ry. Co. to construct single line track on High St. West, city of Moose Jaw, across C.P.R. Outlook Branch, subject to and upon certain conditions.

19860—July 21—Authorizing T., H. & B. Ry. to cross, at grade, highway between Lots Nos. 26 and 27, Con. 3, Tp. Saltfleet, Co. Wentworth, Ont., with a passing siding extending from at or near a point on its main line a short distance west of Stoney Creek station and marked H.B. 1654.14 (mileage 31.33) to a point marked H.B. 1695.72 (mileage 32.12).

19861—July 22—Authorizing C.P.R. to construct spur for Vermont Marble Co., Proctor, Vermont, in city of Peterborough, Ont.

19862—July 23—Amending Order No. 19676, dated June 25th, 1913, by striking out figures "133.0" after word "mileage" where they occur in recital and operative parts of Order, and substituting therefor figures "123.0."

19863—July 21—Authorizing Michigan Central Ry. to construct weighing scales on side track leading into plant of Canadian Shredded Wheat Co. on Lewis Ave., Niagara Falls, Ont., and (2) approving and authorizing clearances of bridge over said scales, as shown on plan.

19864—July 21—Authorizing municipal corporation city of St. Thomas and Board of Water Commissioners of said city, to lay and thereafter maintain an 18 inch water main from St. Thomas Waterworks under M.C.R.R. on Moore St. between Talbot and Centre Sts., and between Moore St and Mill St., and on Mill St. between Centre and Amelia Sts.

19865—July 22—Approving G.N. Ry. Co.'s Standard Passenger Tariff C.R.C. No. 825, applying a maximum rate of 3 cents per mile between stations on its lines as follows:—Brandon, Sask., and Hudson's Bay Ry.; Manitoba Great Northern Ry.; Midland Ry. of Manitoba; Victoria & Sidney Ry., and line of Victoria Terminal Ry. and Ferry Co.; (2) temporarily approving, pending judgment in inquiry into rates charged generally by railway companies in Province of British Columbia, tariff applying a maximum rate of 4 cents per mile to be charged between stations on its lines as follows:—Bedlington & Nelson Ry.; Crow's Nest Southern Ry.; Nelson & Fort Sheppard Ry.; New Westminster Southern Ry.; Red Mountain Ry.; and line of V.V. & E. Ry. & Nav. Co., and (3) said tariff, with copy of this Order, be published in at least two consecutive weekly issues of Canada Gazette.

19866—July 21—Approving, temporarily, pending judgment in inquiry into rates charged generally by railway companies in British Columbia, G.T.P.R. Standard Freight Mileage Tariff C.R.C. No. 17, including and cancelling C.R.C. No. 15, to apply between stations in British Columbia, Prince Rupert to Morricetown, inclusive; said tariff with copy of this Order to be published at in least two consecutive weekly issues of the Canada Gazette.

19867—July 22—Approving location G.T.P. Ry. station at Cooking Lake, mileage 766.1, west of Winnipeg, in Sec. 6-52-20, W. 4 M., Alta.; station to be erected in accordance with company's design "B."

19868—July 23—Extending until Sept. 15th, 1913, time within which interlocking plant be installed at crossing of C.N.R., by G.T.P.R., at Empire Ave., city of Fort William, Ont., required to be installed by Order No. 19352, May 22nd, 1913.

19869—July 22—Approving proposed location C.P.R. station in N.E. ¼ Sec. 10-8-17, W. 2 M., at Trossachs, Sask.

19870—July 22—Authorizing C.L.O. & W. Ry. (C.P.R.) to construct across Ontario St., town of Cobourg, Ont., at mileage 120.20 from Glen Tay, by means of grade crossing.

19871—July 22—Authorizing C.N.O.R. to construct across and divert public road under Mississippi River Bridge, in Lot 22, Tp. Fitzroy, Co. Carleton, Ont., at Station 1812.87.5.

19872—July 23—Authorizing C.N.O.R. to construct bridge to carry its line across Petawawa River (west crossing), Tp. Deacon, Dist. Nipissing, Ont., mileage 159.3, west of Ottawa.

19873—July 23—Authorizing G.T.P. Branch Lines Co. to construct highway between Secs. 25 and 26-35-23, W. 4 M., across its Tofield-Calgary Branch, at mileage 104.5, in Dist. North Alberta, Alberta.

19874—July 22—Authorizing G.T.R. to construct siding for Farquharson-Gifford Co., Ltd., city of Stratford, Ont.

19875—July 22—Authorizing C.P.R. to construct spur for Medina Shale Brick Co., Ltd., and Streetsville Brick Co., Ltd., in town of Streetsville, Ont.

19876—July 23—Authorizing C.P.R. to construct spur for Abernethy & Lougheed, Ltd., in Lot 398, Sec. 12, Tp. 12, N.W.D., B.C., Haney, N.W.D., British Columbia.

19877—July 23—Authorizing C.N.O.R. to construct across public road between Twps. Saltfleet and Grimsby, Cos. Wentworth and Lincoln, Ont.

19878—July 24—Amending Order No. 19593, dated June 16th, 1913, by striking out word "west" in second line of paragraph 1 of said Order, and substituting therefor word "east."

19879—July 23—Authorizing C.P.R. to construct spur for its irrigation department, from a point on northerly limit of its right of way, in S.E. ¼ Sec. 32-18-14, W. 4 M., at Brooks, Alta., to be completed within three months from date of Order.

19880—July 23—Approving revised location G.T.P. Ry. and location of its station grounds, in Sec. 17-43-2, W. 4 M., Alberta.

19881—July 22—Authorizing C.N.O.R. to construct across fourteen (14) highways in Tp. Saltfleet, Co. Wentworth, Ont.

19882—July 23—Approving plans showing overhead highway bridge to be constructed by C.P.R. at Asylum Side Road, at London, Ont.

19883—July 23—Authorizing C.P.R. to construct two (2) bridges (1) No. 33.5, near Cavan station, and (2) No. 5.75, near Norwood station, Toronto Sub-Div., Ontario Division, Ont.

19884—July 23—Authorizing C.P.R. to construct four (4) bridges—Nos. 55.8, near Station Rooth, St. John Sub-Div., Atlantic Div.; 7.1, near Norwood station, Toronto Sub-Div., Ontario Div.; 33.6, near Dunsford, Bobcaygeon Sub-Div., Ontario Div., and 16.9, near Ops, Ont., Bobcaygeon Sub-Div., Ontario Div.

19885—July 24—Recommending to the Governor-in-Council for sanction, indenture of lease, dated June 2nd, 1913, between Kettle Valley Ry. Co., as lessor, and C.P.R., as lessee, executed in duplicate and filed with Board under file No. 11738.79.

(Continued on page 88.)

The Lowest Rate

It is not easy to obtain the lowest possible rate when insuring industrial buildings.

The time to consider the insurance cost is when the plans are being prepared for the building.

Architects can obtain the benefit of our highly-specialized knowledge of insurance ratings and fire protection, with the result that their buildings can be so planned that the insurance cost is as near "nil" as it could possibly be.

In the case of buildings already completed we will make inspection and suggest means of lessening the fire hazard that will likely more than pay for themselves by securing lower insurance rating.

TENDERS CALLED FOR

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

TRENT CANAL.

PORT SEVERN SECTION—SEVERN DIVISION.

NOTICE TO CONTRACTORS.

SEALED TENDERS, addressed to the undersigned and marked, "Tender for Port Severn Section—Severn Division, Trent Canal," will be received at this office until 2.00 o'clock p.m., on **Monday, August 25th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after July 26th at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa; at the office of the Superintending Engineer, Trent Canal, Peterborough, Ont.; at the office of the District Engineer, Public Works Department, Midland, Ont., and at the office of the Postmaster, Orillia, Ont.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labour, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered Bank of Canada, for the sum of $10,000, made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 29th July, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—45677.

SEALED TENDERS addressed to the undersigned, and endorsed, "Tender for East Pier, Eastern Entrance, Toronto Harbour, Ont.," will be received at this office until 4.00 p.m., on **Tuesday, September 2nd, 1913,** for the reconstruction of part of superstructure of East Pier of Eastern Entrance to Toronto Harbour, in the County of York and Province of Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and H. J. Lamb, Esq., District Engineer, Windsor, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering declines to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, August 1, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—43525.

TENDERS FOR PAVEMENT.

Sealed tenders addressed to William Buller, Chairman Board of Works, Peterborough, Ontario, and endorsed "Tenders for Pavement" will be received until 5 p.m., Wednesday, August 20th, 1913, for the construction of Bitulithic and Asphaltic Concrete Pavements on George and Charlotte Streets and for Bitulithic Asphaltic Concrete and Portland Cement Concrete pavements on Hunter Street, Peterborough.

Plans and specifications may be seen at the City Engineer's Office, Peterborough, Ontario. Each tender must be accompanied by an accepted cheque for five (5) per cent. of the amount of the tender.

The lowest or any tender will not necessarily be accepted.

R. H. PARSONS,
City Engineer.

Peterborough, Ontario,
August 5, 1913.

(For Further Tenders see page 88.)

Contractors' Locomotives

6-WHEELED SADDLE TANK SWITCHING LOCOMOTIVE BUILT FOR THE HAMILTON STEEL & IRON CO. LTD.

Diameter and stroke of cylinders 17×24 ins. Diameter of driving wheels 50 ins. Total wheel base 11 ft. Weight of engine in working order 108,000 lbs. Tractive power 21,220 lbs. Tank capacity 850 Imp. gals. Coal capacity 1¼ tons.

We can make excellent delivery of locomotives for every variety of service—for industrial work, mines, contractors, etc. All sizes —all types—all practicable gauges.

Duplicate parts are carried in stock for immediate shipment. We build locomotives to meet the Government regulations of the various Provinces.

We have had fifty years' experience as builders of locomotives. Our expert workmen are in many cases the sons or grandsons of men who worked in our shops many years ago. Combined with this long experience and expert workmanship, we have new equipment, efficient management and expert designers.

Special attention is paid to economy of maintenance; also to design of boiler and fire box to ensure ample steam capacity and economy of fuel. Consult us before purchasing a locomotive!

Handsome catalogue, 108 pages, 38 illustrations, with valuable tables and data, free to engineers, contractors or manufacturers — on request.

4", 5" and 6", Centrifugal Pumps, d.-c. to Vertical Engines (new).
5, 8 and 12 ton stiff leg Derrick Irons (new).

H. W. PETRIE, Limited Front Street W. TORONTO

FOR SALE.—Complete Sewer and Water Contractor's outfit, including one Parsons' Trench Excavator, Trench Braces, Fire Pots, Pumps, etc. For price and terms apply to Navin Bros., Contractors, Moose Jaw, Sask.

FOR SALE at a snap: 60-H.P. Cowan and Co. engine and 80-H.P. Cowan and Co. boiler. Write for particulars, J. F. Barnard and Son, Spencerville, Ont.

Tenders Called For

CAYUGA, ONT.

Sealed tenders will be received up to noon on the 16th day of September, 1913, by the undersigned at Cayuga, Ontario, for the construction of twenty-six and one-half miles of stone macadam road in the county of Haldimand.

The work will be let in three separate and distinct contracts, not necessarily to the same individual.

Tenderers are required to examine the localities of the work and are requested to be present at the opening of the tenders at 2 p.m., on Wednesday, the 17th day of September, 1913.

Plans and specifications may be seen at the office of the County Engineers, Messrs. Jackson and Kyd, Dunnville, or may be had from them on the payment of $10, which sum will be refunded on return of the documents.

Lowest or any tender not necessarily accepted.

T. A. SNIDER, K.C.,
County Clerk,
County of Haldimand,
Cayuga, Ont.

TENDERS FOR CONCRETE BRIDGES.

Sealed tenders addressed to William Buller, Chairman Board of Works, Peterborough, Ontario, and endorsed "Tenders for Concrete Bridges" will be received until 5 p.m., Wednesday, August 20th, 1913, for the construction of a reinforced concrete arch bridge of twenty-six (26) feet span, sixty-six (66) feet long on Park Street and of a reinforced concrete slab and beam bridge of twenty-seven (27) feet span, sixty-six (66) feet long on McDonnel Street. Separate tenders for each bridge shall be made.

Plans and specifications may be seen at the City Engineer's Office Peterborough, Ontario. Each tender must be accompanied by an accepted cheque for five (5) per cent. of the amount of the tender.

The lowest or any tender will not necessarily be accepted.

R. H. PARSONS,
City Engineer.

Peterborough, Ontario,
August 5, 1913.

(For further Tenders see page 86.)

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

(Continued from page 84.)

19886—July 24—Extending, until Aug. 31st, 1913, time within which C.P.R. and G.T.R. Co.'s install bells at crossing of Perth Road by their railways, one mile north of Kingston, Ont.

19887—July 24—Extending until October 31st, 1913, time within which C.P.R. install gates at crossing Centre St., Chatham, Ont.

19888—July 23—Approving location G.T.P. Branch Lines Co. station at Siding No. 7, Sec. 10-45-23, W. 3 M., Sask., mileage 47 on its Cut Knife Branch.

19889—July 24—Extending time within which G.T.R. install interlocking plant at Paris, Jct., Ontario, until Oct. 15th, 1913.

19890—July 24—Authorizing Chatham, Walaceburg & Lake Erie Ry. Co. to take, for purposes of convenient accommodation of the public and traffic on its railway, and to secure efficient maintenance and operation of its railway, Lot 18, city of Chatham, Ont.

19891—July 24—Approving location C.N.R. station at Radville, Sask.

19892—July 21—Authorizing M.C.R.R. to construct extension to siding, from present terminus thereof, on Moore St., between Centre and Talbot Sts., St. Thomas, Ont., northerly along Moore St., a distance of 28 ft. to a point distant 20 ft. from southerly limit of Talbot St.; to be completed within three months from date of this Order.

19893—July 24—Directing G.T.R. to install Hoschen type of electric bell at crossing of Mill St., town of Milverton, Ont., and thereafter maintain bell at its own expense; detail plan showing layout to be submitted for approval of an engineer of Board within 30 days, and work be completed within 60 days from date of this Order; 20 per cent. of cost of installing bell to be paid out of the Railway Grade-Crossing Fund, and remainder to be paid by railway company.

19894—July 24—Approving location C.P.R. proposed new station on S.W. ¼ Sec. 30-9-26, W. 4 M., at Nolan, Alberta.

19895—July 24—Directing G.T.R. remove board fence and cut down hill, or bank, on right of way, at Marsh Winery Road, Stamford, Ont., for a distance of 930 ft., so that no portion of said bank be more than 4 ft. above level of track.

19896—July 25—Approving proposed location C.P.R. station on Sec. 34-4-3, E.P.M., Man., at Arnaud, subject to condition that company construct suitable sidewalk and driveway from station to north side Smith Ave., and maintain same until land east of roadway is subdivided and taken over by the municipality; or that in the alternative Railway company be at liberty to construct sidewalk and driveway on its right of way; station to be erected in accordance with C.P.R. Standard Structural Plan "A2."

19897—July 25—Approving By-Law No. 14 (superseding By-Law No. 11), passed at meeting of directors of G.T.P. Ry., held on 16th July, 1913, authorizing J. E. Dalrymple, vice-president, and A. E. Rosevear, general freight agent of company, to prepare and issue tariffs of tolls to be charged for carriage of traffic over company's railway or any portion thereof, and rescinding Order No. 15186, dated Oct. 25th, 1911.

19898—July 25—Authorizing James Bay & Eastern Ry. Co. to construct across con. road, mileage 38, side road, mileage 38.7, Mill road, mileage 39.3, road to Mt. Albert, mileage 40.35, side road, mileage 40.6, and side road, mileage 41.6, Tp. of Gwillimbury, Co. York, Ontario.

19899—July 25—Authorizing G.T.P. Branch Lines Co. to carry passenger traffic over portion of Tofield-Calgary Branch, between Trochu, mileage 121.4, and Beiseker, mileage 162.6, Alta.; provided trains be operated over said portion at a speed not exceeding 12 miles an hour.

The debris shown at the left of this photograph carried away a steel bridge, but was powerless to hurt this concrete bridge. At one time the water was higher than the arch rings and flooded right across the approaches.

Concrete Defied the Flood

FIREPROOFNESS has been perhaps the greatest reason for the rapid rise of concrete in the favor of builders.

Another striking advantage has been demonstrated. Tornadoes have left concrete structures standing alone amidst the ruins of other buildings.

And now the greatest flood the world has seen in years has added "flood-proofness" to concrete's established list of merits.

Concrete buildings in the flooded districts of Ohio and Indiana suffered practically no damage—Concrete bridges withstood the terrible pressure of millions of tons of water and held firm under the terrible strain of debris that pounded itself to pieces in futile effort to destroy.

DO YOU NEED MALE HELP.—Canadian or foreign labor furnished for all classes of work, skilled or unskilled, for office, construction work, waterworks, paving, dams, and wharves. We can put men on the job for you cheaper than you can get them any other way, write or phone for particulars to O'Donnell's Employment Bureau, 116 Wellington Street West, Toronto. Phone Adelaide 3919.

ELECTRICAL AND MECHANICAL ENGINEER,—25 years' experience, desires superintending position. First-class references. Electric lighting, power, mining, or similar line of work preferred. Please address Box 62, *The Canadian Engineer*, Toronto.

EXPERIENCED ENGINEER desires appointment, preferably as municipal or sanitary engineer. Technical education; twenty years' experience in the design and construction of drainage, sewerage and sewage disposal systems; street and road construction. Also limited experience in topographical surveys, water supply, town planning and plumbing design. Member of the American Society of Civil Engineers, and of the Royal Sanitary Institute. Please address replies in first instance to Box 66,, *The Canadian Engineer*, Toronto.

ENGINEERING SALESMAN open for engagement. Excellent experience in selling mill power and mining machinery. Good references. Will be pleased to keep any appointment made through Box 70, *The Canadian Engineer*, Toronto.

ENGINEER WANTED.—For erection of refrigerating, pumping and power plants with a Western Canadian Company, some commercial and drawing experience preferred. Must invest One Thousand Dollars ($1,000.00). Box No. 98, *The Canadian Engineer*, Toronto, Ontario.

MAN, (40), with university and technical education, engineering experience, both office and field, desires employment with Civil Engineer, or would become articled to Dominion Land Surveyor. Can report immediately. Presently residing in Winnipeg, will go anywhere. Box 100, *The Canadian Engineer*, 820 Union Bank Bldg., Winnipeg.

MECHANICAL ENGINEER—Experienced Designer, Cost Estimator and Salesman, Works Supervision, all kinds of steam engines, boilers, hydraulic pumps, air machinery and mining plants, seeks position with Consulting Engineer, Contractor, Manufacturers or agency business. Highest references, some capital. Box 102, *The Canadian Engineer*, Toronto.

REINFORCED CONCRETE ENGINEER, 27, married, graduate, broad experience capable of designing and estimating all kinds of structures, buildings, tanks, jetties, bridges, grain elevators, retaining walls, etc., possesses initiative and ability to meet architects, engineers and contractors, best references, wants responsible position with reinforced concrete firm or contractor. Box 104, *The Canadian Engineer*, Toronto.

PATENT NOTICE.—Notice is hereby given in regard to Canadian patents 100,707, 100,980 and 129,756, steam turbines, and 135,000, 135,001, 136,321 and 137,222, classifiers, that Canadian Allis-Chalmers, Limited, Toronto, owner of rights under said patents, is prepared to supply devices covered by these patents.

NOTICE.—Anyone desiring to obtain the invention covered by Canadian Patent No. 134877, granted on August 8th, 1911, to Adolph A. K. Nowak, for Pilger Rolling Mills, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh and Smart, Castle Building, 53 Queen Street, Ottawa, Ontario. Russel S. Smart, Resident.

NOTICE.—Anyone desiring to obtain the invention covered by Canadian patent No. 135037, granted on August 15th, 1911, to Thomas Martin Sandiford for Apparatus for Lighting and Extinguishing Gas Lamps, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh and Smart, Castle Building, 53 Queen Street, Ottawa. Russel S. Smart, Resident.

ELECTRIC FURNACE.—The proprietors of Canadian Letters Patent No. 134,772 of 1911, are prepared to sell, or license Canadian manufacturers to work in Canada, this patent, which relates to a furnace to be used for the refining of steel or for other refining or smelting operations. Address, International Acheson Graphite Co., Niagara Falls, Ont.

PATENTS.

Below will be found a complete list of patents recently granted to inventors in Canada and United States, which is furnished by Messrs. Fetherstonhaugh & Co., patent barristers, solicitors, etc., head office, Royal Bank Building, 10 King Street East, Toronto. Offices in Hamilton, Montreal, Ottawa, Winnipeg, Vancouver and Washington, D.C., from whom all information may be readily obtained.

Canadian Patents.

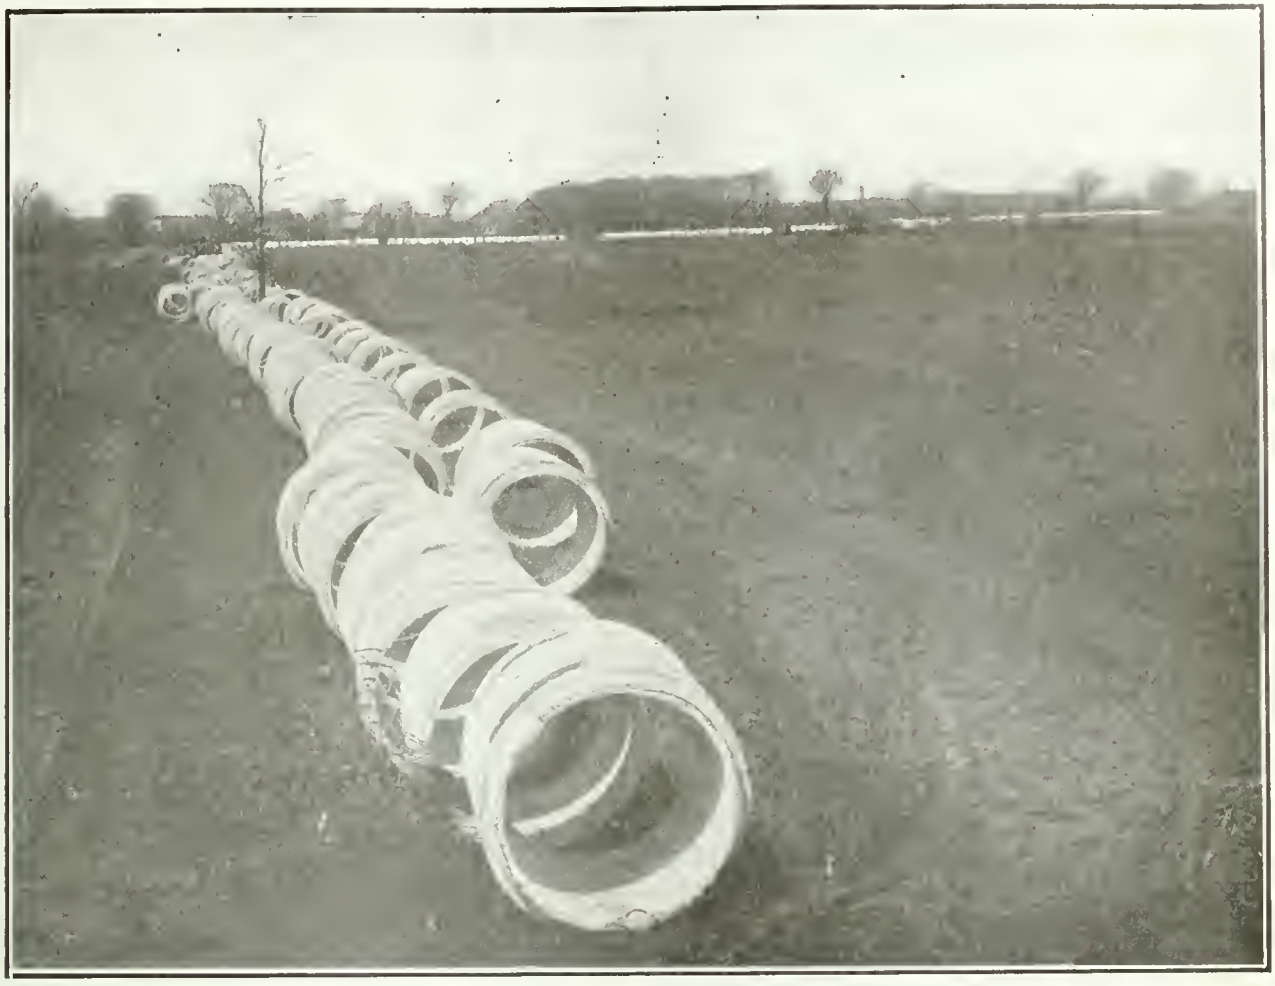
S. Schopflocher, composition for flooring and the like; W. P. Armstrong, dummy figures; F. A. Winterson, lanterns; A. Hackett, steam generators; A. Hilliard, combination tools; H. C. Jarvis, wall paper display standards; A. E. W. Langford, attachments for stoves; G. P. Maud, swinging stall-posts; B. Moore, stove pots; G. W. Morey, baby jumpers; N. E. Nash, boiler feeding apparatus; T. G. Priestland, devices for opening or closing screw-sealed vessels; A. E. Trentowsky, cooking utensils; F. A. Warner, sounding devices; I. Therrien, smoke consumers.

United States Patents.

A. S. Hamilton, detonator magazine; I. Therrien, smoke consumers.

AMERICAN CONCRETE INSTITUTE.

The first annual Convention of the American Concrete Institute, which is in reality the tenth Convention of the National Association of Cement Users, the name having been changed by amendment of charter on July 2nd last, will be held in Chicago, February 16th to 20th, 1914, and promises to be one of the most successful and important in its history. Announcements will be made from time to time as to programme and other features.



54-inch pipe distributed for sewers at Montreal, Canada.

MERIWETHER SYSTEM

CONTINUOUS RE-INFORCED

CONCRETE PIPE

PATENTED

LOCK JOINT PIPE COVERS NORTH AMERICA

Sewage flowing through Lock Joint Pipe reaches the Atlantic Ocean, Pacific Ocean, Gulf of Mexico, Hudson's Bay and the Great Lakes.

Lock Joint Pipe is in use for sewers and water conduits in the following States: Connecticut, Delaware, Florida, Georgia, Illinois, Indiana, Kansas, Kentucky, Maryland, Massachusetts, Michigan, Missouri, New Hampshire, New Jersey, New York, Ohio, Oregon, Pennsylvania, South Carolina, Texas, Virginia, Washington.

The following Provinces of Canada: Quebec, Ontario, Saskatchewan, Alberta and British Columbia.

And in the Island of Cuba.

The Lock Joint Pipe Company is the largest manufacturer of reinforced concrete pipe in the world.

MARKET CONDITIONS

Montreal, August 2nd, 1913.

Prices hold very steady, being again unchanged, as follows:—

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ¼ base; tire steel, $2.30 for 1 x ¼ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is unchanged, being now per 100 lbs., as follows:—¼-in., $5.30; 5-16-in., $4.70; ⅜-in., $3.90; 7-16-in., $3.65; ½-in., $3.55; 9-16-in., $3.45; ⅝-in., $3.40; ¾-in., $3.35; ⅞-in., $3.35; 1-in., $3.35.

Copper.—Prices are 16¼c. Excellent demand.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are: Queen's Head, $4.35; Colborne Crown, $4.25; Apollo, 10¼ oz., $4.25. Add 25c. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lead.—Prices are firm at $5.35.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $2.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is active and strong:—$36 for 6 and 8-inch pipe and larger; $37 for 4-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the followiog is 73½ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.40; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73½ per cent. for black and 63½ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, August 6th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16½ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ¼ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1¼ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in., $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Clevelaod, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.30	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gange, $2.80; 26-gange, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, August 5th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $12.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie nut, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.90; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gange, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gange American, $5.15; Fleur de Lis, 22 to 24-gange, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.90; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 13½c.

Tool Steel.—8½ to 15c. per pound

RAILWAY TRANSPORTATION PROBLEMS OF THE FUTURE

PRECEDENTS OF PIONEER RAILROADING OVERTURNED BY NEW FACTORS—THE QUESTION OF GRADES A HANDICAP TO CO-OPERATION—SYSTEM OF GRADE PROFILE ANALYSIS IN NEED OF REVISION—ELECTRIC TRACTION SHOULD NOT BE DELAYED.

By J. GRANT MACGREGOR, C.E., Mem. Can. Soc. C.E.
Chief Engineer, The Alberta Central Railway Company.

THE building of so many transcontinental lines across the Dominion, and the opening up of new inland and ocean waterways for the transportation of the produce of the country may be regarded as the dawn of a new era in the history of railway transportation.

The rapidity of the pace set by competitive lines is in a measure responsible for the state of bewilderment in which the country now finds itself when confronted with the most important railway building and transportation problems of the age. The situation has been the subject of much controversy both among members of the engineering profession and those concerned financially in the economics of present-day railway construction and operation. Precedents based on past experience in pioneer railroading have been disregarded, and the researches and life work of the greatest authorities on railway economics have been found antiquated when compared with the progress of recent events.

There is also a decided lack of harmony between different departments of the various railways in regard to the advantage of the present practice of building railways with long stretches of low ruling grade, all of which tend to unnerve the engineer who may have placed too much faith in the adaptability of old and well-known rules to modern conditions.

The question that now arises is, to what extent are the conditions changed that require a departure from well-known rules and practice in railroad building. The two greatest factors that have entered into, and hold sway in all problems of railway engineering and operation since the invention of steam, are those of "Tractive Power" and "Train Resistance," and as long as the law of gravitation exists we shall have at least one of them to contend with. In considering the other factors, the development of steam tractive power and its application to overcoming train resistance, we find that no great strides have recently been made whereby increased efficiency in the hauling power of locomotives should bring about a change in the conditions affecting grade and alignment. Until closer co-operation is instituted between the operating and engineering departments of the various railways very little will be accomplished in the way of building railways on a basis by which the best results can be obtained in their operation. Too frequently is advantage taken of a new line with low grades as an accessory for the use of old or obsolete engines whereby a saving can be affected to the operating department at the expense of the construction department.

If by constructing railways with lower ruling grades a solution is not obtained to the problem of hauling heavier train loads with present engine efficiency, then a step has been taken in the wrong direction, which is not at all unlikely. The solution, however, will not be found in any further development of the increased weight of the present unit of steam tractive power. More likely it shall be found where a greater number of units are used whether of steam, electrical or oil gas propulsion, whereby the load to be hauled can be increased to a proportion consistent with the proper train unit for minimum cost of operation.

But, to return to the question of the value of lower ruling grades, it should not be necessary at the present time to make a strong plea for their use wherever they can be introduced at a reasonable cost. The fact that millions are being spent annually by the various trunk lines on grade reduction should be sufficient evidence that the movement has got beyond the experimental stage. The wisdom of such a course is apparent from the beneficial results obtained in the way of increased revenue and lower cost of operation. The changes and modifications of grade profile designed to produce the beneficial results obtained have invariably been based on well-known rules in railway location and data obtained from experiments of the actual performance of trains under the conditions sought. If there should be any uncertainty about the continuous performance or endurance of certain classes of locomotives on long stretches of low ruling grades the sooner the value of such a factor is taken into account the better. In the meantime, are we to assume that the defect is of a mechanical nature and that, until such time as it can be removed the grade profile should be modified to provide suitable resting places for the recuperation of the "old horse"?

Under present conditions what is most urgently required is a more definite system of grade profile analysis, by which the proper amount of tractive power can be as-

signed to the requirements of each division of road to be operated. The analysis referred to once carefully prepared and put in graphic form should show the performance of each class of engine between stations, with a load line adjusted to conform to the requirements of minimum speed over long stretches of ruling grade. To obtain satisfactory results close co-operation is necessary between all departments affected.

The growth of the trade of the Dominion affecting transportation companies is so rapid that greater caution than ever should now be exercised in constructing new arteries of commerce. It would appear that in determining the main arteries of commerce of the future, greater consideration should be given to conditions affecting their future development than to questions of rapid transit and shortest route under present conditions. The fact must not be overlooked, however, that there will always be a limit to the extent to which physical obstacles can be removed from a route, and for this reason it may be necessary to look for developments along other lines. Some of the sources from which relief must be expected are already to some extent receiving attention from the principal transportation companies, such as greater facilities for a more speedy and continuous flow of traffic in both directions along the main arteries, with corresponding facilities for the better handling of freight at distribution and terminal points.

If the demand, however, for increased train loads should continue to find favor a change in the present principle of the application of tractive power to the hauling of trains must be expected. It is to be hoped the day is not far distant when it will be found more economical to combine the power now developed by such a huge fleet of locomotives into stationary engines for the distribution of power in a manner better adapted to modern requirements so that it shall no longer be necessary to have one or two portable power houses attached to each train unduly wasting the products of our mines and diffusing the sparks which destroy the combustible products of the forests and prairie.

THE USE OF EXPLOSIVES.

The mining engineering profession is accustomed to consider the use of high explosives as its especial field. It is probably not generally realized how widely explosives are used otherwise. Disregarding the strictly engineering work of excavation in rock or compact material on a considerable scale, explosives are finding an increased application in more varied lines. Dynamite seems to be not only available, but highly efficient for such purposes as extracting stumps; breaking subsoils to assist drainage and the entrance of plant roots; digging post holes; ditching, especially for drainage purposes; blowing out holes for planting trees; breaking up unwieldly boulders and excavating in connection with road work.

The National Paving Brick Manufacturer's Association will hold its tenth annual meeting at Cleveland, Ohio, on September 17 and 18. This is the first summer convention the association has held, the former custom of holding winter meetings having recently been altered to afford opportunity for investigating actual work on brick street and road construction. Officers of the National Paving Brick Manufacturers' Association are:—Charles J. Deckman, Cleveland, president; Will P. Blair, Cleveland, secretary.

INSULATION OF JOINTS IN PIPE LINES.*

By William R. Conard,
Inspecting Engineer, Burlington, N.J.

SOME years ago it was the writer's privilege to secure pipe for carrying high-pressure gas, or rather that was the term used in speaking of it, and the thought was that it might be of interest to the New England Waterworks Association to have a short description of the manner in which these pipes were laid in an endeavor to get a line as nearly proof against electrolytic action as possible.

The pipe were of the ordinary bell and spigot type with the bell made 5 in. deep and with no lead groove (see Fig. 1), and were tested to 50 lb. of air per sq. in. at the foundry in addition to the regular hydrostatic test. In all there were about 15 miles of 6-in. pipe.

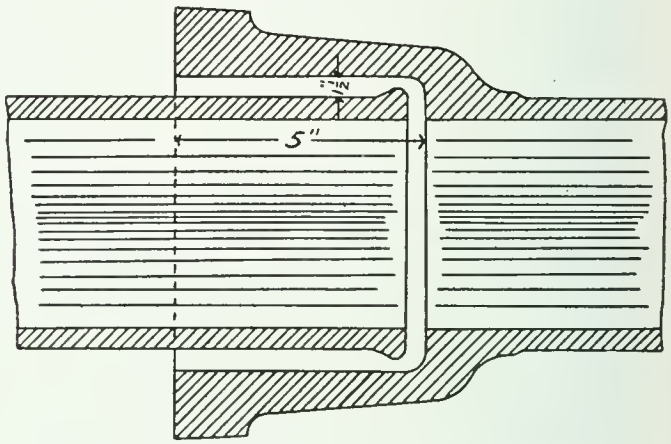

Fig. 1.—Cross-Section of Bell and Spigot.

In laying these pipe the joints were made up by placing at the base of the bell ¼-in. wooden ring, oil-soaked; the spigot of the pipe next to be used was then encircled with a rubber band about 1/16 in. thick and 2½ in. wide placed about 5½ in. from the spigot end of the pipe to prevent an iron ring, afterwards put on, coming in contact with the pipe; the pipes were then put together, the spigot going home against the wooden ring, and about 1½ in. of untarred jute packing calked tight; instead of lead being poured in to make the rest of the joint, an insulating compound about 3 in. deep, black in appearance, which melts readily at 200° F., was poured, after which a square rubber packing was put on, and then a No. 4½ Dresser coupling was applied to the joint and clamped tight (see Fig. 2).

To those unfamiliar with the Dresser coupling, it may be described as consisting of two split clamp rings; one split clamp ring fitting around the outside of the base of the bell, the other around the outside of the spigot end of the pipe, entering the bell, with a 1-inch square rubber packing ring between it and the bell. The two rings are connected and drawn towards one another by four bolts, one ring pressing against the square rubber packing.

The line, after laying and in sections, was tested with 20 lb. per sq. in. air pressure, and all the joints found tight.

Joints made up in this manner are as flexible as poured lead joints, acting just as readily as expansion joints,

*Read before the New England Waterworks Association, February 12, 1913.

and electric tests made shortly after installation indicated no flow of electricity at all, although, the entire pipe line parallels an electric car line.

The expense of a line like this figured about three times greater than for an ordinary lead joint, but for a gas line it was considered very desirable that it should be no conductor of electricity.

It is probably true that the rubber used in these joints will in time disintegrate, but it is also true that it will last for quite a number of years, for the moisture in the earth and the absence of exposure to the atmosphere should keep the volatile particles of the rubber alive for a long while.

As an insulated joint to prevent pipe lines from carrying stray currents of electricity it would appear that it would be fully as serviceable for water as for gas lines.

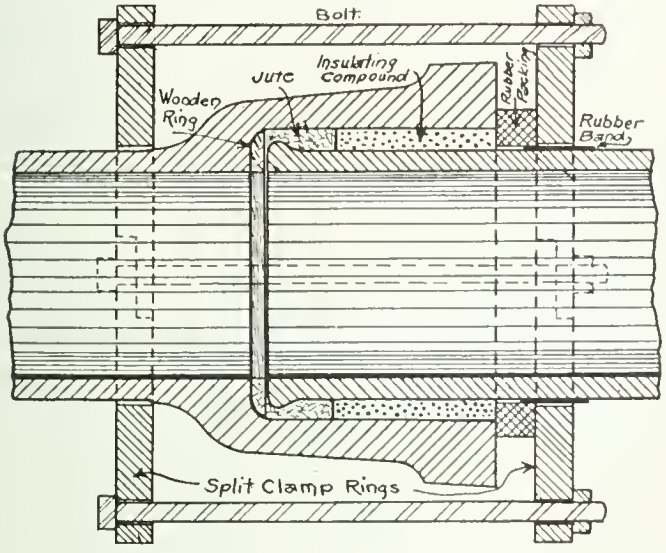

Fig. 2.—The Joint Constructed.

Since writing the above I learn from Mr. Brackett, chief engineer of the Metropolitan Waterworks, that rubber insulated joints have been used by them and were successful when installed, but due to a large amount of current charging the pipe from a heavy electric storm, the rubber was in part carbonized and thereby became a conductor rather than an insulator. It would appear, therefore, that so long as electricity can be prevented from collecting in large volume, the joint described is an efficient insulator, but one can never tell what is going to happen during an electric storm. If the rubber once becomes carbonized or loses volatile properties, it fails as an insulator.

The Lincoln Highway Association, formed to secure the establishment of an ocean-to-ocean highway, to be a memorial to Abraham Lincoln, has established headquarters at Detroit. The highway, plans for which are nearing completion, is to cost approximately $10,000,000, of which $4,200,000 has already been subscribed. The association proposes to co-operate with local communities in procuring the establishment of the highway, to be engaged in the improvement or reconstruction of existing highways, which will constitute a part of the route. Several States along the line have already taken steps towards the construction of improved highways from east to west to connect with the coast-to-coast route. Mr. H. B. Joy is president of the association.

THE SYDNEY COAL FIELDS.

By Joseph G. S. Hudson.

THE mines branch, Department of Mines, Ottawa, in a bulletin specially prepared for the International Geological Congress, by Mr. J. G. S. Hudson, gives some interesting historic facts concerning the Sydney coal fields of Cape Breton, Nova Scotia. The sketch is as follows:—

The maritime provinces of Canada, owing to their geological position on the Atlantic seaboard, were the first in Canada to have their mineral resources explored. Among these resources coal is one which stands pre-eminent, and Nova Scotia has for over 200 years had an enviable reputation as a producer of bituminous coal.

The first printed notice of the existence of coal in these areas appeared in 1672, when Nicholas Denys published in Paris, "La Description Geographique et Historique des Costes de l'Amerique Septentrionale." Eighteen years before, in 1654, Denys had obtained from Louis XIV., a concession granting the right to explore and work mines of gold and other minerals; for this privilege he agreed to pay the King a royalty of one-tenth. In 1677, M. Duchesneau, the Intendant of New France, issued a proclamation, exacting a royalty of 20 sous per ton, from all persons taking coal from Cape Breton. In 1711, Admiral Walker—who commanded an expedition to reduce Quebec—mentions in his journal, that he procured a supply of coal from the cliffs, with no other appliances than crowbars.

The initial attempt at systematic mining was made in 1720, when it was found necessary to procure a supply of fuel for the men who came from France to lay the foundations of the fortress of Louisburg. The pit openings then made, can be seen even at the present day, at Port Morien, Table Head, and other places. During the next 100 years, very little work was done, the coal mined being used almost exclusively by the garrison at Halifax. In 1820, however, when Cape Breton Island became part of the province of Nova Scotia, a considerable tonnage of coal was being mined. In 1827 all the mines were transferred to the company known as the General Mining Association by the London firm of goldsmiths (Rundle, Bridge, and Rundle) who had secured the mines and minerals concession for the entire island province of Cape Breton, from the Duke of York. The new owners immediately organized, opened out, and systematically operated, mines in Cape Breton, Pictou, and Cumberland counties. A formidable agitation had been started in the province for some years previous to 1858, claiming that the monopoly of the coal lands by the General Mining Association was seriously retarding the legitimate expansion of the coal trade; this agitation eventually resulted in the whole subject being referred to the privy council of Great Britain for equitable adjustment. In 1858, the Mining Association surrendered its claims to the provincial government of Nova Scotia. The government, in return, agreed to abolish the fixed rental of £3,000 per annum, together with the royalty on slack coal; to reduce the royalty on all screened coal up to 250,000 tons, to 4.80 pence per ton; and to reduce the royalty on all coal sold over 250,000 tons to 3.20 pence per ton. To the association, however, was reserved the exclusive right to 20 square miles in Cape Breton, and to 4 square miles each in Pictou, Joggins, and Springhill counties respectively. Under this new regime, mining developed to such magni-

tude that, in 1865, the provincial government appointed an inspector of mines (John Rutherford, M.E.)—the first on this continent.

In, 1854 the government of the United States removed the duty on coal. This "open door" policy greatly increased the trade with the New England States; in 1866, the exportation of coal thereto amounted to 404,252 tons. In 1867, however, (year of Confederation) the United States once again discriminated against Canadian coal, imposing a duty of $1.25 per ton. This duty was maintained at this rate until 1872, when it was reduced to 75 cents per ton; at which figure it remained until 1894. During this latter period, the exports fluctuated from 228,132 tons to 13,883 tons. During the period 1894-97, the tariff was reduced to 40 cents, but in 1897 it was advanced to 67 cents, at which figure it still remains. Notwithstanding the tariff barriers, the exportation of Nova Scotia bituminous coal to the New England States continued to increase, and in 1903 the shipments reached a maximum of 968,832 tons. There has been a gradual decrease since that date, and in 1912 the shipments were 412,531 tons. The total production has, however, increased enormously; in 1912 it was 6,802,997 tons (of 2,240 pounds). Of this production 5,197,601 tons are to be credited to the coal fields of Cape Breton.

This marked increase in the production is due in part to the increased market offered by St. Lawrence ports. In 1877 a select committee of the Dominion parliament, appointed to inquire into the condition of the coal trade, recommended the imposition of a duty on United States coals; this duty has had the desired effect of opening up the markets of the St. Lawrence to the Nova Scotia coal trade, and in 1912 the St. Lawrence market alone purchased 2,159,005 tons, most of which came from Cape Breton.

On February 1, 1903, the Dominion Coal Company was organized with a capital of $18,000,000 by a special Act of the Legislature of Nova Scotia. This corporation amalgamated the principal interests in the coal areas on the south side of Sydney harbor, Cape Breton. These included the Caledonia, International, Gardiner, Old Bridgeport, Glace Bay, Reserve, Gowrie, Victoria, and Ontario mines, also the Sword areas, in all comprising 70 square miles; the areas controlled have now been extended to 142 square miles. With the advent of this great industrial organization, a new era in Nova Scotia coal mining began; new mine workings, railway extensions, new shipping and discharging facilities were developed, old coal markets were expanded, and new ones opened out, so that the whole coal trade was revolutionized. In the first year of its operations (1893) the coal mined was 834,019 tons; in 1912, the production amounted to 4,332,320 tons; or an increase of nearly 520 per cent. in 20 years.

In 1900, the Nova Scotia Steel and Coal Company acquired all the mining rights still held by the General Mining Association. In addition to operating the existing collieries, they have opened out new mines, erected iron and steel works, and built a modern coke oven plant, all in close proximity to the working collieries. Their Princess Pit—now known as Sydney No. 1—was, in 1873, the first submarine mine in North America, the coal being won from workings under the sea. The shafts are of unique construction, consisting of metal cribbing or tubbing. The total length of metal tubbing is 842 ft. 9 ins., weighing some 776 tons. Here, also, was erected the first Guibal ventilating fan in Cape Breton.

The most important of the Cape Breton coal fields is that known as the Sydney field. It is an extraordinarily rich tract of coal bearing rocks, having an area of approximately 250 square miles. It extends along the northern coast of Cape Breton island for a distance of about 35 miles. Geologically the coal bearing strata are bounded by the outcrops of the Millstone Grit, as seen at Mira Bay, and they terminate at Cape Dauphin, where the intrusive syenites of the Ste. Anne hills form the northern boundary of the Great Bras d'Or Lakes. The Sydney field is divided into four main basins, as follows:

(1) Cow Bay or Morien Basin, defined on the east by the Millstone Grit and on the west by an anticlinal fault that dips seaward at Cape Percy.

(2) Glace Bay Basin, bounded by the Cape Percy anticline on the east, and by the Bridgeport anticline on the west.

(3) Lingan-Barasois—Victoria Basin. This basin has not so well defined boundaries as the two preceding basins but it extends from Bridgeport anticline, passing the eminence known as David Head, to a submerged fault which exists midway in Spanish Bay and Sydney Harbor.

(4) Sydney Mines or Bras d'Or Basin. This basin extends from the submerged fault in Spanish Bay to the western termination of the coal measures at Cape Dauphin.

Mr. Richard Brown, the well-known author of "The Carboniferous System of Cape Breton," states that the thickness of the productive measures of the Sydney field will not exceed 6,000 feet. This measurement is taken from Burnt Head in the Glace Bay Basin, where the highest known bed occurs, down to the Millstone Grit. It is possible that the extended deep workings at this point may, in the future, accurately determine their actual thickness.

The bulletin includes a set of summary records of analyses of Sydney coals, and fifteen plates of sections of coal seams and strata, some of them representing a depth of over 1,500 feet. An index map of the fields is appended.

Logan Waller Page, Director of the United States Office of Public Roads, will read a paper at the Road Congress at Detroit on the "Selection of Road Materials." Before he was appointed to his present post Mr. Page assembled at Harvard University the first road material testing laboratory in America, following his studies at the French School of Roads and Bridges, and his name is now identified with some of the best-known apparatus for road material tests. The selection of road materials is an exceedingly important factor in the building of a road, and it is certain that Mr. Page's paper will receive the closest attention.

The world's largest power plant is projected to be located at Big Eddy, on the Columbia River, a few miles above the Dalles. The gorge at this point is of such a character that comparatively little work will be required to impound a great quantity of water, sufficient to develop 300,000 horse-power. The river can be entirely closed by the construction of a dam only 300 feet long and 180 feet above its foundations, and the construction of a canal 300 feet wide, 20 feet deep and a mile and a half in length. The head of water is 73 feet at low tide and 42 feet at high water, and the mean flow of the river throughout the year is 235,000 cubic feet per second. The hydro-electric units would be each of 32,000 horse-power. The total cost of the scheme would be about $23,000,000.

DESIGN AND GRAPHIC METHOD FOR CALCULATING A STEEL TRUSS.

By Leonard Goodday, C.E., M.E.,
Late of the British Admiralty.

IT is very well known by engineers that the graphic method is the best, quickest and most practical way for calculating the various stresses on the different members in steel work, etc., the diagram showing at a glance what the actual stress is on each strut or tie. The following is for a truss which was calculated some years back for the roof of a gymnasium built for the accommodation of 1,600 naval cadets. The building is 136 ft. 6 ins. by 60 ft. in the clear, the trusses being placed 10 ft. 6 ins. apart, so that there are 12 trusses in all. Fig. 1 shows details of design for one half span, and also stress diagram.

Starting with the weight on the truss, and taking the wind into account, dead weight, when worked out, equals 55.8172 lbs. per sq. ft. Superficial area equals 10.5 × 35.125, or 368.85 sq. ft., from which the total weight is found to be 9.20 tons. The truss is of the Warren type, and the distributed weight equals 0.92 tons at each end of half span, and 1.84 tons on each apex.

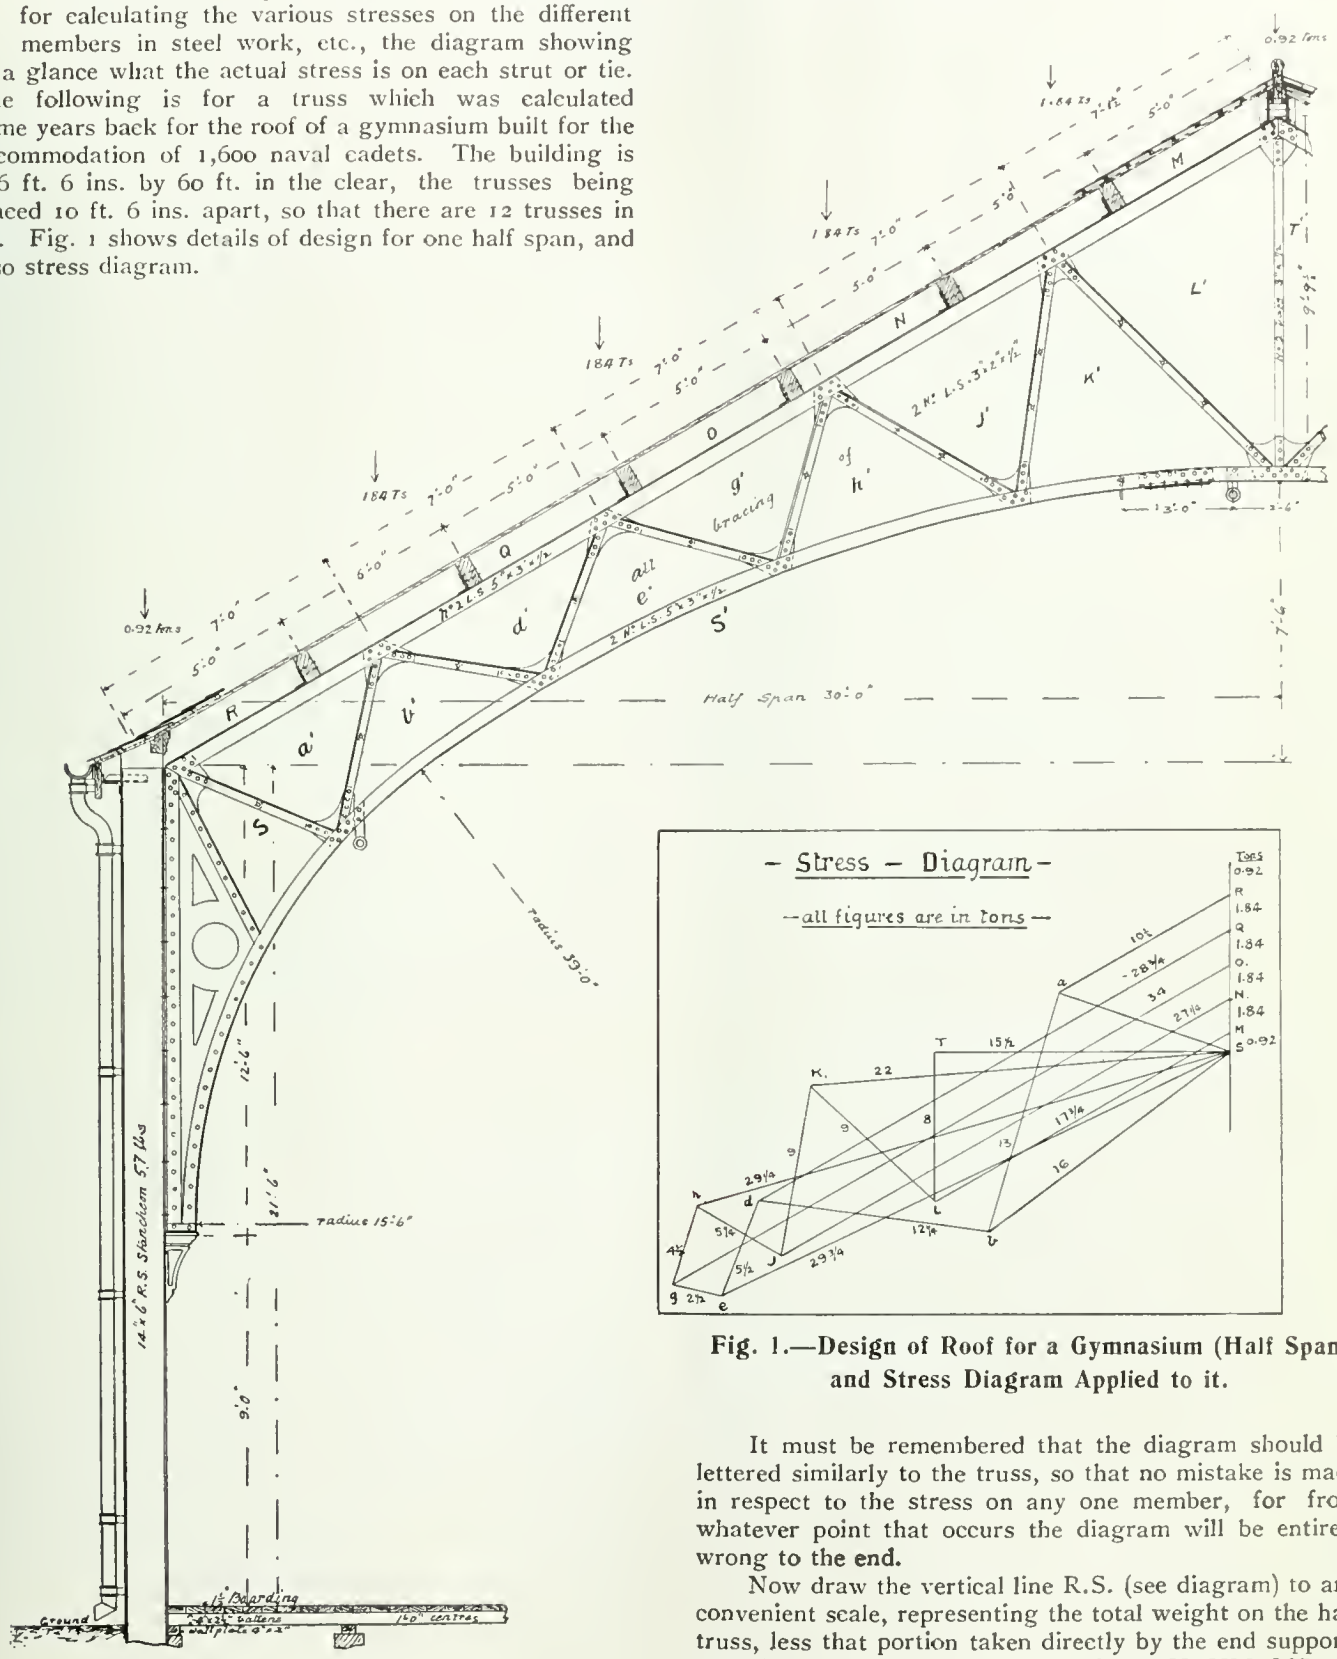

Fig. 1.—Design of Roof for a Gymnasium (Half Span) and Stress Diagram Applied to it.

It must be remembered that the diagram should be lettered similarly to the truss, so that no mistake is made in respect to the stress on any one member, for from whatever point that occurs the diagram will be entirely wrong to the end.

Now draw the vertical line R.S. (see diagram) to any convenient scale, representing the total weight on the half truss, less that portion taken directly by the end support, and divided into the lengths RQ, QO, ON, NM, MS, re-

presenting the various weights in tons, as shown. It will be noticed that the lettering of the panels, and the naming of a member by the letters on either side simplifies the process throughout.

From R	and	S	draw	Ra, Sa,	parallel to	Ra′	and	Sa′	on sketch	until	they	intersect	at	a
" a′	"	S	"	ab, Sb	"	a′b′	"	Sb′	"	"	"	"		b
" Q	"	b	"	Qd, bd	"	Qd′	"	b′d′	"	"	"	"		d
" S	"	d	"	Se, de	"	Se′	"	d′e′	"	"	"	"		e
" O	"	e	"	Og, eg	"	Og′	"	e′g′	"	"	"	"		g
" S	"	g	"	Sh, gh	"	Sh′	"	g′h′	"	"	"	"		h
" N	"	h	"	Nj, hj	"	Nj′	"	h′j′	"	"	"	"		j
" S	"	j	"	Sk, jk	"	Sk′	"	j′k′	"	"	"	"		k
" M	"	K	"	ML, KL	"	ML′	"	K′L′	"	"	"	"		L
" S	"	L	"	ST, LT	"	ST′	"	L′T′	"	"	"	"		T

S′ represents the curved tie in each panel. The stress on each member in the truss is represented by the line parallel to it in the diagram, i.e., stress in K′L′ equals 9 tons and in M′L′ equals 17¾ tons, etc.

The check on the diagram can be seen at once, as the lines TL and TS representing the tension on the vertical and horizontal members at centre will also be vertical and horizontal respectively. These stresses can also be calculated mathematically as a further check.

The accompanying table shows the actual sectional area required for the various members.

The holes for rivets are generally made ⅛ in. larger in diameter than the rivets.

The plates at joints are ½ in. in thickness. In no cases should they be less than ⅜ in., otherwise they are liable to cut through the rivets. Cutting the plates to the shape shown makes a far neater job, makes the truss lighter, and looks more workmanlike. The larger rivet of ⅞ in. makes a better "snap," and each head has a better grip, which makes the structure more rigid and less likely to wear lose, and consequently makes the truss more durable. The bracings should be neatly chamfered at the ends, so that the flats can fit properly together, and have a good bearing with the plates. The riveting should be carefully done so as to fill the holes, otherwise they are not reliable. In heavy work extra rivets are put in to allow for defective work, especially in girder work. This work was made extra stiff to allow for vibrations which would be caused by the trapeze which were slung from the main ties by rings fixed for that purpose.

Lastly, one of the main points to be observed in constructing the stress diagram is to work from the eaves, and to have three forces complete at each step.

Table Showing Sectional Areas and Scantling.

	Principal and bottom curved tie									Bracings									
Scantling	Ra′	Qd′	Og′	Nj′	ML′	bs′	e′s′	h′s′	K′s′	Sa′	a′b′	b′d′	d′e′	e′g′	g′h′	h′j′	j′K′	K′L′	L′T′	T′S′
Stress in tons	10½	28¾	34	27¼	17¾	16	29¾	29¼	22	9½	13	12¼	5½	2½	4½	5¼	9	9	8	15½
Net area required	1.8	4.8	5.7	4.5	3.0	1.7	5.0	5.0	3.7	1.6	2.2	2.0	0.9	0.4	0.8	0.9	1.5	1.5	1.3	2.6
Gross area required	No. 2 ⅞" rivets area = 1.20 + 5.7 = **6.9 gross**									No. 2 rivets = 1.20 + 2 + 2 = **3.4 gross area**										
Bars at centre	No. 2 ⅞" rivets area = 1.20 + 1.3 (L′T′) = **2.5** against No. 2 vertical bars at centre = 2 × 3 × ½ = **3.0**																			
Principals, &c.	No. 2 L.I.S. 5" × 3" × ½" = 2 (5 + 2½) × ½ = **7.5 sq. ins.**—No. 2 L.I.S. 3 × 2 × ½ = 2 (3 + 1½) × ½ = **4.5 sq. ins.**																			

The stress allowed in this case is 6 tons per sq. in. It will be noticed that stress on the different panels for the principal and curved or main tie naturally changes at each end, and also for the bracing, and that, for economy as well as simplicity in construction, it is always best to have one sectional area only. Consequently the greatest stress in each case is taken, i.e., for the principal and curved tie 34 tons is taken, and for the bracing 13 tons. This becomes 5.7 and 2.2 sq. in. respectively when worked out, and, adding in each case 2 holes of ⅞ in. diameter, the final results amount to 6.9 and 3.4 sq. in. gross area respectively. It will be seen that the principals and curved ties composed of No. 2 L.S. 5 in. by 3 in. by ½ in. gives 7.5 sq. in., against 6.9, and that the bracing composed of No. 2 L.S. 3 in. by 2 in by ½ in. equals 4.5 sq. in., against 3.4. At the centre of truss L′T′ has a tension of 1.3 tons and for two rivet holes 1.20, so that the total amounts to 2.5 sq. in., and No. 2 vertical tension bars having 3.0 sq. in. will be about right. The rivets should never be less than ⅞ in. for this span of 60 ft., although ¾ in. diameter rivets are sometimes used, but then more rivets are needed at the joints, and consequently the plates are much larger and therefore clumsy. In work of this kind it is not always wise to consider the rivets in double shear where this occurs, as practically no rivet is ever sheared in two places at once. It must be remembered that at the joints there must be enough rivets in the end of each bracing or tie to take the thrust or pull in either case. The pitch of rivets for the principals and curved or main tie equals 3½ ins., and for the bracing 2⅝ ins.

A new hard alloy of platinum has been produced by Dr. Fritz Zimmerman, of Newark, N.J., by the addition of osmium. It is claimed that this alloy, containing from one-half to 10 per cent. of osmium, having physical and electrical properties fully equal to the platinum alloy containing a much higher percentage of iridium.

September 22nd, 23rd and 24th are the days of the annual meeting of the American Mine Safety Association, the membership of which is composed of coal and metal mine operators, mining engineers, etc., and having for its object the reduction of the number of accidents in mines and quarries. The Convention will be held in Pittsburg, Pa. An interesting paragraph in the prospectus recently issued is the following: "Since fifty-eight per cent. of all industrial accidents are shown by statistics to be due to negligence, carelessness or lack of knowledge of employers or employees, the vital necessity of learning everything possible about the causes and means of preventing these accidents must be evident to every man concerned in mining. To the operators it spells business success or failure; to the miner, life or the physical ability to work and support a family."

THE CONTROL OF RIVER FLOODS.*

By Col. C. McD. Townsend, M.Am.Soc.C.E.
United States Corps of Engineers.

THE subject of land drainage is intimately associated with that of river improvement. The cultivation of the soil largely increases the amount of sediment entering our streams; the direction of the furrow markedly affects the amount of rainwater that flows from its surface, and every ditch or subsurface drain promotes a more rapid flow into our rivers during floods and possibly affects their discharge during low water. On the other hand, no satisfactory system of land drainage can be accomplished in a country subject to periodic overflow by river floods. In the Mississippi Valley protection from floods is absolutely required before any regular system of drainage can be inaugurated. The overflow is so great and the amount of sediment carried by the river so large, that the drains would be annually destroyed or filled. The floods not only insure the destruction of any crops that might be planted, but also usually occur at such times as to prevent the harvesting of a second crop the same year.

Sources of Floods.—Before entering upon such a discussion of the means of preventing these floods, it is desirable to have a clear conception of the sources from which floods arise. The greater Mississippi Valley is bounded on the east by the Appalachian chain and on the west by the Rocky mountains. These mountain ranges exert a great influence on its floods. The winds blowing from an easterly direction deposit most of the moisture they absorb from the Atlantic Ocean on the eastern slope of the Alleghenies, and therefore cause little rain in the Mississippi Valley; the Rocky Mountains intercept the moisture from the Pacific Ocean. While showers occur from winds blowing over the Great Lakes, the original source of the floods of the Mississippi is to be sought in the Gulf of Mexico.

During the winter and spring the land of the Mississippi Valley, no matter what its soil or the nature of its covering, is cooler than the waters of the gulf, and a southerly wind becoming saturated with moisture as it passes over the water will precipitate that moisture on the land in copious rains, or in snow when the temperature is sufficiently low. A wind from the southwest sweeps up the Ohio Valley; one from the south carries moisture to the Upper Mississippi; one from the southeast to the valleys of the Arkansas and the Missouri; but in all cases there is a tendency for the greatest rainfall to occur near the coast, and gradually to decrease as the wind currents travel inland.

Generally speaking, the rainfall is very unequally distributed over the Mississippi Valley, being least at the upper sources of the tributaries, and rapidly increasing as the main stream is reached, though an exception is to be noted in the southern tributaries of the Ohio, whose sources are nearer the gulf than are their outlets.

The maximum discharge of the Upper Mississippi River is estimated at 450,000 second-feet; the Missouri, 900,000; the Ohio, 1,400,000; the Arkansas, 450,000; and the Red, 220,000. There is also a large discharge from the Yazoo, St. Francis, White, Tensas, and Ouachita rivers. The maximum discharge of the Mississippi during the flood of 1912 was about 2,000,000 second-feet at Cairo, and 2,300,000 at the mouth of the Red River. It overflows its natural banks when the flow exceeds 1,000,000 second-feet.

While the influence of forests on stream flow has received little attention in this country until recently, the scientists of Europe have discussed the subject pro and con during the past forty years. It is generally accepted by both sides that the leaves falling from forest trees as they decay form a humus which has a large capacity to absorb water, and that when the forests are felled this humus is seriously injured by forest fires. It is also admitted that snow is more rapidly melted when it is exposed to the direct rays of the sun in an open field than when sheltered from such action in the forest. In fact, it has been found by the United States forestry service from experiments recently made in the White Mountains that the flow from cleared fields under such conditions is about twice that from forests. The forest advocates claim that this is sufficient proof that forests absorb water during flood periods, which percolates through the ground and flows from springs later in the season, thus reducing flood heights and increasing the low water flow of rivers. Its opponents do not admit that the problem is thus easily solved. They claim that floods do not arise from the melting of snows by the direct action of the sun; that this process is so slow that the water which flows off would not raise a river to mid-stage; that floods occur when on a layer of snow there falls a copious supply of rain, and both the rain and melted snow enters the stream simultaneously; and that under such conditions the forest, instead of being beneficial, is injurious. On cleared land the wind tends to blow the snow from the ridges and piles it in immense masses in the ravines, while in the forests the snow is uniformly distributed. A few days of sunshine dries out the ridges in the open field and melts sufficient snow in the forest to saturate with water the underlying humus.

If a heavy rainfall then occurs, the forest humus, being saturated, can absorb no more water, and the combined rain and snow of the forest flows into the streams, while in the cleared land, the ridges having dried out, absorb a large portion of the rainfall, and the snowdrifts expose a much smaller surface to the action of rain. Moreover, during periods of great drouth the forest humus and long, deep tree roots also absorb more water than grass and farm crops, and retard the run-off at a time when it is most needed for low water navigation. They therefore maintain that a forest is a fair-weather friend of some use in regulating the mid-stages of a river, but an utter failure when most needed—that is, during extreme floods or extreme low water. While I consider this discussion valuable, my objections to reforestation are not based solely on a scholastic argument.

It requires from twenty to fifty years to produce a good forest growth, and over a century for the leaves of that forest to decay in sufficient quantities to produce the humus which will be satisfactory as an absorbent of rainfall. We can not afford to delay the drainage of the Mississippi Valley even to produce the forest growth, without taking into consideration the time required for the humus to form. We are more vitally interested in the height that the river will attain in the next few weeks than in what will occur in the year 2013.

It is also pertinent to this discussion to determine what would be the extent of the forest reservation which would be required to reduce the flood heights on the Mississippi River a given amount. To solve this problem

*Paper read at a recent meeting of Drainage Congress in St. Louis.

it is necessary to make certain assumptions, and for purposes of argument we will take it for granted that reforestation will reduce the flood discharge of a stream one-half. The Mississippi flood of 1912 attained the greatest height of any then recorded at all gauge stations, except at Vicksburg. That of January and February, 1913, while 5 feet lower at Cairo, was the next highest flood at Memphis, and for a considerable distance along the river. We will endeavor by reforestation to reduce the flood of 1912 to the heights attained in the winter of 1913. For this purpose it will be necessary to reduce the maximum discharge of the river 500,000 second feet. It will also be necessary to distribute this reduction among the tributaries, reducing the maximum discharge of the Missouri River from 900,000 to 700,000 second-feet, that of the Upper Mississippi from 450,000 to 350,000, and that of the Ohio River from 1,400,000 to 1,200,000.

As stated in the introductory remarks, the flood discharge of the Missouri River at its headwaters is about 1 cubic foot per second per square mile of drainage area, and if the reduction in discharge of one-half is to be secured by reforestation 2 square miles of forest would be necessary for every second-foot of reduction of flood discharge, or 400,000 square miles of forests to reduce the discharge of the Missouri River 200,000 second-feet. At the headwaters of the Upper Mississippi the ratio of flood discharge to drainage area is about 2 second-feet per square mile. A reduction of this discharge by one-half would require a forest reservation of 100,000 square miles to reduce the floods of the Upper Mississippi 100,000 second feet. On the Ohio River the ratio is six to one, and it would therefore require forests at the headwaters of the Ohio having an area of 66,000 square miles to reduce its flow 200,000 second-feet. In other words, to reduce the height of a flood at Memphis by reforestation at the headwaters of the river from that of 1912 to the next highest on record would require a forest reservation of about 566,000 square miles, an area exceeding that of the portions of Montana and Wyoming drained by the Missouri River and North and South Dakota, the portion of Minnesota drained by the Upper Mississippi River, and the States of Wisconsin, Iowa, Illinois, and Indiana. But even such a forest reservation would afford only partial protection, and large expenditures for levees would still be required. Under the above assumptions, to prevent any overflow by reforestation would necessitate a practical abandonment of the valley for agricultural purposes, and the development of an extensive irrigation system to produce tree growth in arid regions of the west.

It is therefore apparent that even under the most extravagant claims of forestry advocates, reforestation as a means of reducing flood heights on the Mississippi requires the conversion of too much farming land into a wilderness to be practicable. The waste land that can profitably be converted into forest reservations is too limited in area to produce an appreciable effect on the floods.

Reservoirs.—To have retained the Mississippi flood of 1912 within its banks would have required a reservoir in the vicinity of Cairo, Ill., having an area of 7,000 square miles, slightly less than that of New Jersey, and a depth of about 15 feet, assuming that it would be empty when the river attained a bank-full stage. If the site of such a reservoir was a plane surface, the quantity of material to be excavated in its construction would be over 100,000,000,000 cubic yards; and its estimated cost from 50 to 100,000 million dollars. Such a volume of earth would build a levee line 7,000 miles long and over 150 feet high.

Cairo is the logical location for a reservoir to regulate the discharge of the Lower Mississippi. It will not only control the floods from the Ohio, but also the discharge from the Missouri and Upper Mississippi. But if the reservoirs be transferred from the mouths of the tributaries to the headwaters, their capacity must be largely increased. No two floods have the same origin, unless they are referred back to the Gulf of Mexico. The wind bloweth where it listeth. If the prevailing winds in the early spring are from the southwest, the southern tributaries of the Ohio furnish the crest of the year's flood; if more nearly from the south, reservoirs will be required on the streams of Ohio, Indiana, and Illinois; a slight varying of the wind will produce a flood in the Upper Mississippi, while if it blows from the southeast the principal sources of trouble will be the Red, Arkansas, and Missouri rivers. To control the flow of every stream in the Mississippi Valley by reservoirs is a pretty large job, even for the United States Government, but that is what the control of the Mississippi during floods by reservoirs signifies.

The advocates of the control of the floods of the Mississippi by reservoirs do not, however, have in mind any such radical control as is above indicated. They limit the control to the headwaters of the various tributaries, and while every stream that flows in the valley may be considered a headwater of some tributary, I judge from the discussions of the reservoirs and their proposed employment for power purposes, which requires a considerable height of dam, that by headwaters is meant the sources of the rivers in mountainous countries as distinguished from the more level plains, and more specifically the sources of the Missouri above the mouth of the Yellowstone, those of the Upper Mississippi in the State of Minnesota, and those of the Ohio in the Appalachian range.

The flood which is now devestating the country affords data for determining the effect of such a system of reservoirs and its lessons are the more valuable because no effort is necessary to refreshen the memory. When, on April 2, the gauge at Cairo attained a height of 54 feet, there was flowing down the Mississippi River at least 2,000,000 cubic feet of water per second. It requires about eleven days for a flood wave to be transmitted the 966 miles between Pittsburgh, Pa., and Cairo; on March 22, the Pittsburgh gauge read 5.3 feet, which is produced by a flow in the Ohio River at that locality of about 15,000 second-feet. In ten days a flood travels the 858 miles between St. Paul, Minn., and Cairo; on March 2 the reading of the St. Paul gauge was 0.5 foot, corresponding to a discharge of the Mississippi of about 2,500 second-feet. In eight days the effect of a flood at St. Joseph, Mo., is felt at Cairo; on March 25 the gauge at St. Joseph read minus 0.1 foot, representing a discharge of the Missouri River of about 17,000 second-feet. If a system of reservoirs had been constructed which would have prevented all flow from the Allegheny, the Monongahela, the Mississippi above St. Paul and the Missouri above St. Joseph, it would have reduced the 2,000,000 second-feet discharged by the Mississippi River at Cairo on April 2 less than 35,000 second-feet.

The water which passed Cairo on the 2nd of April came principally from the White and Wabash, and the lower tributaries of the Ohio, and after the water of these rivers started to subside the flood from Cincinnati, though increasing from 57 to 69 feet on the gauge, could

increase flood heights at Cairo less than 1 foot. The flood of 30 feet at Pittsburg on March 28 produced its effect on the Cairo gauge on April 8. It has merely prolonged the flood without increasing its height.

The proposed system of reservoirs would have cost hundreds of millions of dollars and its effect on this year's flood height of the Lower Mississippi could not possibly have exceeded 6 inches.

Neither the rain nor snow which falls upon the mountainous portions of the Mississippi watershed has much effect upon the floods of the lower river. The principal source of the floods is the great alluvial plain between the mountains. As pointed out, excepting the southern tributaries of the Ohio, the rainfall is relatively slight at the upper sources of the tributaries and their maximum flood discharge does not usually coincide with that of the mid-valley.

Great floods do not arise from average conditions, but from exceptional variations such as are caused by a series of heavy rains rapidly succeeding one another. Each rainstorm starts down a stream a flood, the volume of which can be absorbed by a reservoir with comparatively little trouble, but if a second storm sweeps over the valley the reservoir to be effective must be emptied or its capacity doubled. To hold all the excess rainfall till low water would require reservoirs of enormous capacity. Economic considerations usually require that the reservoirs should be emptied as soon as the crest passes, in order to utilize the same space for a second rainfall; so that while reducing the crest of a flood at a given locality they necessarily prolong the period during which the river remains at a high stage.

The water which is abstracted from the Gulf of Mexico is usually precipitated in the Mississippi Valley within a period of two days. The return flow extends over a period of two or three months. The sum of the maximum discharges of the various tributaries of the Mississippi River is nearly 4,000,000 second-feet, while the greatest measured discharge of the river itself is about 2,300,000. This apparent discrepancy arises from the fact that the floods of the tributaries do not reach the gulf at the same time. The crest of the Ohio River flood usually passes down the river in March or April, that of the Missouri in May or June. Moreover, the same law applies to the tributaries of a tributary. The waters of the southern branches of the Ohio tend to discharge into that river before those in Ohio, Indiana, and Illinois.

By the construction of reservoirs, this beneficient law of nature is deranged. Instead of the crest of the flood of one stream passing down the river before that of another reaches it, two prolonged high stages will obtain which will tend to synchronize and the resultant combination may be higher than either flood would have been by itself.

A system of flood control designed to be satisfactory for one city may be most disastrous to another locality further down stream. If a system of reservoirs had been in operation in the Allegheny and Monongahela rivers during last January, it would have protected Pittsburgh from overflow and diminished the flood at Cincinnati when it was 50 feet on the gauge, but only to increase it when it attained a height of 60 feet. And this effect would have been propagated to the gulf.

Pittsburgh, moreover, would never consent to such a manipulation of reservoirs on the upper tributaries of the Ohio as would insure the reduction of floods at Cincinnati or on the Lower Mississippi. Source stream control on the Mississippi River and its tributaries would therefore soon reduce itself to the question, Whose ox is to be gored?

Levees.—While the use of forests or reservoirs as a means of flood control is still in an experimental stage all over the world, the employment of levees for this purpose has been tested for centuries. The Po, Rhine, Danube, Rhône, and other rivers of Europe have been successfully leveed. The laws governing the flow of water in a confined stream have been carefully studied and the construction of levees is just as susceptible of mathematical analysis as other engineering problems. There is an element of uncertainty in all the forces of nature. No one can say positively, for instance, that St. Louis may not at some future time experience an earthquake or a cyclone of greater intensity than that which swept the city in 1896 There is also a possibility that there will be some combination of meteorological conditions which will create a flood of greater volume than has heretofore occurred in any drainage area. But the height to which levees should be constructed is as susceptible of determination as the strains to be permitted in an office building due to wind pressure or the moving load allowable on a bridge. The city engineer solves a similar problem whenever he constructs a sewer to carry off the storm water from the city streets.

Nor is there any evidence either that floods have been increasing in recent years, due to the cutting off of forests or that the beds of our main rivers are rising as they are leveed. The effect of forests on rainfall in Europe has been carefully investigated by Profs. Schlichting and Hagen. The records at London, Paris, St. Petersburg, and other localities where the rain has been recorded for long periods fail to show any tendency to an increased fall in recent years.

The meteorological records of the United States have not been maintained a sufficient length of time to be of much value in solving the problem. Such data as we possess indicate that the flood discharge has not increased in recent years. The greatest flood of the Mississippi at St. Louis occurred in 1844, the next largest in 1875. On the Great Lakes the high water of 1838 is the greatest on record. In the Ohio the flood of 1884 exceeded that of 1913 at Cincinnati, and that of 1832, while 5 feet lower at Cincinnati, was 5 feet higher at Pittsburgh than this year's flood. The gauge records at the bridges over the Upper Mississippi, which cover a period of thirty years, would indicate that the flow from Minnesota and Wisconsin, where the forests have been most extensively destroyed during the period, has been slightly improved, though the river shows signs of deterioration where it receives the flow from the prairie lands of Iowa and Illinois.

On the Merrimac River where the mill owners have accurate observations extending back to 1849 there appears to be some increase in flood discharge, though reports of the forestry commission of the State of New Hampshire and census returns from the State of Massachusetts indicate that the forest area of its basin is 25 per cent. greater than forty years ago, due to the abandonment of farms. Such records as we have in this country appear to confirm the conclusions of the German forestry authorities that the influence of forests on drainage is concealed by other causes more powerful in their effects.

The flood of 1912 was not due so much to excessive precipitation as to the fact that the surface of the ground was still frozen over the States of Illinois, Indiana, and Ohio, so that there was not the soil absorption of rain water that usually occurs.

There is not the remotest connection between deforestation and the disasters which have just occurred at numerous cities in Ohio and Indiana. The flood of 1832 was similar to that of 1913, but it was discharged by streams of the dimensions the Creator intended they should have. Since then cities have sprung up and land has become so valuable that riparian owners have encroached upon the waterways. Where the floods formerly flowed untrammeled, factories and dwellings have been constructed and numerous bridges have further restrained the stream's discharge.

The question of the rise of the river bed by levee construction has been exhaustively investigated. On the Rhine the maximum effects were observed at Dusseldorf, where the same discharge at low water appears to attain a height 8 inches greater to-day than it did one hundred years ago, while the same discharge at high water has lowered about 1 foot in a century. On the Po the maximum observed change in low-water conditions was 0.02 of a foot per year, but it is by no means proved that even these small changes have resulted from levee construction. They may have arisen from the improvements in the river bed which were made simultaneously with levee construction. The observations of the Mississippi River Commission agree with the Dusseldorf observations, in that the Mississippi River appears to be slightly enlarging its section, at least at mid-stages.

The present contents of the adopted levee line of the Mississippi River is about 243,000,000 cubic yards. It has been computed that with an addition of 200,000,000 cubic yards and at an estimated cost of $57,000,000 this line would be safe against any flood which has occurred in the Mississippi River. This sum, though large, is less than $4 per acre of land protected from overflow, and appears insignificant when compared with the amounts which are being expended per acre for irrigation purposes in the arid west. The increase in the value of land or the damage caused by one overflow like that of 1912 would pay for the completion of the levee system.

When a levee line contains but one-half the material that safety requires, crevasses afford no argument against levee construction. During the flood of 1912 hundreds of miles of levees were topped with earth in sacks to a height of from 2 to 4 feet, to prevent the water flowing over them, and water was seeping through their narrow bases in copious streams, which was unheeded until mud began to flow. The levee which failed at Beulah, Miss., this winter was held till the pile of sacks exceeded 20 feet in height.

The holding of 1,525 miles of such levees through the flood of 1912, even though 13 miles failed, is a powerful argument in favor of a properly constructed levee line. There was no failure where levees were built to a suitable grade and adequate dimensions, as in the Upper Yazoo District.

Conclusion.—While of the opinion that levees afford the only practicable method of controlling the floods in the case of the Mississippi River, I am strongly in favor, nevertheless, of both reforestation and reservoir construction, but limited to the purposes for which they are adapted, just as I am in favor of reinforced concrete for small bridges, though not considering it applicable to one spanning the lower Mississippi River. The price of lumber to-day is a sufficient argument for planting trees, without attempting to associate forestry with the climate or with the flood conditions of our rivers. If the Federal Government or the states do not conserve the forests, the time will soon come when the farmer will raise his crop of timber just as he now plants a field of wheat, and for the same reason, because it will pay him to use his waste land for the purpose.

Reservoirs are necessary for municipal water supplies, for purposes of irrigation, for the development of power and for feeders to canals. They can be successfully employed on small streams to diminish floods or increase the low-water flow. The trouble arises when an attempt is made to utilize them for too many purposes at the same time. There must be a paramount issue to which the others will be subsidiary.

If the main purpose is to supply a city with water only the excess can be used for power development. If the dams are constructed to produce power, the reduction of floods and the improvement of river navigation must be subordinate thereto. Water required for irrigation can only be used to develop power when the dam of the storage reservoir is given a greater height than is necessary for its flow over the land to be reclaimed.

During the next decade there will be an enormous development of reservoirs both for irrigation and for power purposes, which I hope will be utilized to correct man's folly and prevent many disasters similar to those which have recently occurred in Indiana and Ohio.

MINERAL PRODUCTION IN BRITISH COLUMBIA.

The year 1912 was exceedingly favorable to mining in the province and the mineral production made therein was the greatest in the history of its mining, according to statistics contained in the annual report of Wm. F. Robertson, provincial mineralogist for the Province of British Columbia. The gross value of the mineral production for 1912 was $32,440,800, an increase over that of the year 1911 of $8,941,728, or about 33.3 per cent. The greatest output formerly made was in 1910, amounting to $26,377,066, which is exceeded by the production of 1912 by $6,063,734, or 23 per cent., thus showing by comparison, even with what had been the record year, how much the mineral production has increased during the past year. The tonnage of ore mined in the lode mines of the province during the year 1912 was also greater than ever before, amounting to 2,688,532 tons, exceeding the greatest tonnage formerly mined in any year—1910—by 472,104 tons, equivalent to 21.3 per cent. increase.

As compared with the year 1911, the tonnage mined last year shows an increase of 917,777 tons, or about 52 per cent. The tonnage mined in 1912 was produced by the various districts in about the following proportions: Boundary, 74.00 per cent.; Rossland, 9.07 per cent.: The Coast District, 8.03 per cent.; Slocan District, 5.07 per cent.; Nelson, 1.94 per cent.; East Kootenay, 1.87 per cent. and all other parts of province combined, 0.02 per cent.

An electrical process for purifying clay, brought to the notice of the English Ceramic Society by Dr. W. R. Ormandy, depends upon the fact that clay is electro-negative, while its chief impurities are electro-positive. The emulsified clay is partially coagulated by adding electrolytes, and is further purified by passing through a vessel having electrodes differing by 60 to 100 volts. The clay-substance, with as little as 18 to 20 per cent. of water, is deposited as a continuous blanket 4½ feet wide and a quarter of an inch thick. Even fine particles are removed and the solid product may contain as much as 99.5 per cent. of china-clay.

POINTS IN THE PROGRESS & INSPECTION OF SURVEYS

HISTORICAL SKETCH OF THE GROWTH OF THE DEPARTMENT OF THE INTERIOR, SURVEYS BRANCH — REMUNERATION FOR SURVEYORS — POINTS WHERE CONTRACTOR AND INSPECTOR SOMETIMES DIFFER.

By E. W. HUBBELL, L.D.S.,
Chief Inspector of Surveys, Canada,

THE Department of the Interior was established July 1st, 1873, the first Minister being the Hon. Alexander Campbell, who had under his control the following branches of the service:—

1. The affairs of the N. W. Territories.
2. The lands and affairs of the Indians of Canada.
3. The ordnance and Admiralty lands and all other public lands, not under the control of the Department of Public Works, or of those of Militia and Defence, and Marine and Fisheries.
4. The Crown Lands in Manitoba and the N. W. Territories, styled "Dominion Lands."
5. The Geological Survey of Canada.

Prior to the first of July, 1873, the management of the N. W. Territories and the Lands and Affairs of the Indians, devolved upon the Department of the Secretary of State for the provinces, to which department the Geological Survey was attached. On the other hand, the Dominion Lands and the Ordnance and Admiralty were under the control of the Secretary of State for Canada.

In July, 1869, instructions were issued by the Minister of Public Works to Lieut.-Col. Dennis, P. L. Surveyor, requesting him to suggest a scheme or system upon which to base the surveys of the West. This was done and approved, and the survey of the Principal Meridian by Milner Hart and A. C. Webb was the first survey performed under authority of the Dominion Government, in the Territories. At this time the outbreak known as the Red River troubles occurred, and put an end to further surveys for the time being.

In 1870, no surveys were undertaken.

In March, 1871, Col. Dennis was appointed the first Surveyor General of Dominion Lands, and during the same month the administration of the Dominion Lands was transferred to the Department of the Secretary of State, and the Dominion Lands Branch was created. The first Manual of Surveys for the guidance of surveyors was issued in this year, and instructions were given to twenty-one surveyors, Mr. Lindsay Russell being appointed Inspector of Surveys.

In 1872, Captain Cameron, R.A., British Commissioner, was appointed in conjunction with the Hon. Archibald Campbell, named by the United States Government, to determine in accordance with the Second Article of the Convention of London of the 20th October, 1818, the International Boundary Line between Canada and the United States, from the northwest point of the Lake of the Woods, due south to the 49th parallel of latitude, thence westward to the Rocky Mountains. Along the south of the province of Manitoba, iron pillars were placed at two-mile intervals, west of the province the line was indicated by cairns, generally three miles apart.

*Paper read at 7th Annual Meeting of the Association of Dominion Land Surveyors, March 5th, 1913.

In this year instructions were issued to Mr. W. S. Gore, P.L.S., to survey certain reserves granted to the Hudson Bay Company. The first map to show the results of the surveys of Dominion lands was issued this year with the surveyor general's report, also the first official map of the province of Manitoba.

In 1871-72, all surveys were performed by contract, at so much per mile, but in 1873 all the surveyors except those employed in subdivision, were paid by the day.

During this year (1871), 3,800 miles were surveyed and surveyors were paid as follows, all under contract:—

	Prairie.	Poplar woods.	Heavy timber, windfalls, etc.
Block surveys	$9.00	$15.00	$25.00 per mile
Subdivision surveys	$7.00	$11.00	$18.00 per mile

In April, 1872, an Act was passed called the Dominion Lands Act, in which the manner of administrating the lands in Manitoba and the N. W. Territories was dealt with and the system of survey explained. The Act also provided for a Board of Examiners, who were to examine candidates for admission to practice as deputy surveyors, and provided for the admission to practice of surveyors from the different provinces.

In May, 1873, the bill creating the Department of the Interior was assented to, and on the 30th June the management and control of Dominion lands was transferred from the Department of Secretary of State to the Department of the Interior. The Geological Survey was also attached to the department, as was the administration of Indian affairs.

It might be of interest to note here two important Acts passed by Parliament. 1st, in 1873 an Act authorizing the establishment of a mounted police force in the Territories. We all know the incalculable value this magnificent field force (since its inception) has rendered our great country, and whose jurisdiction now extends to Hershel Island in the Arctic Circle. 2nd, in 1874 an Act prohibiting the importation into and manufacture in the N. W. Territories of all intoxicating liquors. This Act was rescinded in 1891.

In this year (1873), the first surveys of Indian reserves were undertaken, six surveyors being employed for that purpose, and on the 28th February, 1874, an order-in-council was passed authorizing a special survey of bases and meridians through the N. W. Territories, and extending to the Peace River. This important survey was placed under the control of Mr, Lindsay Russell, assistant surveyor general, and carried on for some years, one of the assistants being Mr. W. F. King, D.T.S.

It may be of interest to know that from 1871 to 1876, the cost of block outlines averaged $36.83 per mile. The cost of subdividing blocks of four townships into sections and quarter sections was 2.91 cents per acre, adding the cost of the block lines to the above acreage rates made the

total cost of all the township lands surveyed to date (1876), to be 3.83 cents per acre.

In 1877, the Geological Survey became a branch of the Interior Department and the Museum was moved from Montreal to Ottawa.

In 1878, the charge of the N.W.M.P. was transferred from the Department of Secretary of State to the Interior Department. In this year, Col. Dennis was made Deputy Minister of the Interior and Mr. Lindsay Russell became surveyor general.

In 1879, a new branch was erected and added to the department, called the School Lands Branch.

In 1880, the Indian branch was created a separate department and assumed control of the Indian reserves in Manitoba and the North West Territories which had been carried on by the surveyor general.

The surveys of this year have consisted of two classes, outline, or governing ones, performed under the system of daily pay and allowance of actual expenditure incurred, and the subdivision surveys under contract, at rates of so much per mile for certain kinds of work; the rates of the latter having been fixed by competitive tender.

In 1881, 55 surveyors were engaged, 6,400 miles of meridian and outlines were run, and 16,800 miles of subdivisions.

Road allowances were reduced from 1.50 chains in width to one chain, and three of the east and west road allowances in a township done away with.

A new edition of the Manual of Survey was issued containing many improvements and much information to surveyors, as well as several useful tables prepared by Messrs. Deville and King, who were in this year appointed inspectors of surveys, succeeding Messrs. A. H. Whitcher and Milner Hart.

In 1882, Mr. Deville was appointed chief inspector of surveys and took charge of the surveys branch of the department, and Mr. Lindsay Russell became Deputy Minister of the Interior.

An important change this year was the substitution of iron posts for wooden ones at the section corners, the markings for each corner were stamped on a square tin about six inches square, placed over the bar and fastened to it by a nail.

In order to prepare the number of copies of township plans required, it was found necessary to establish a lithographic office in connection with this branch. Plans were printed by a cheap process, and although not presenting the appearance of good lithography from engraved stones, they met all requirements.

On the 8th of May an order-in-council was passed dividing the North West Territories into four provincial districts, called respectively Assiniboia, Saskatchewan, Alberta and Athabasca.

In 1883, 119 surveyors were employed. The extensive operations (the greatest on record) during this year and the previous season became necessary owing to the rapid construction of the Canadian Pacific Railway, which in the fall of this year, reached the Rocky Mountains. During the season surveying operations were conducted on a gigantic scale, over 70,000 miles were surveyed, providing 27,000,000 acres of land for the agriculturist.

Owing to the rapid growth of work in the department, the offices of Deputy Minister and Surveyor General, held by Mr. Lindsay Russell, were separated. Mr. Russell remained surveyor general, and Mr. A. M. Burgess became Deputy Minister of the Interior. The supervision of the surveys at headquarters was under the control of Mr. Deville, chief inspector of surveys, while Mr. King, inspector of surveys, had the direction of the operations in the field, and a third edition of the Manual of Surveys was issued.

In this year we have our first information regarding the examination of survey contracts.

In 1884 the Settlement Act was passed by the British Columbia Government, and the transfer under its provisions to the Dominion Government of a belt of land 20 miles in depth on both sides of the Canadian Pacific Railway was effected, and surveys within this belt were commenced, also the survey of old trails in the Territories.

In June, Mr. Lindsay Russell, surveyor general, retired from service on account of ill-health.

In 1885, owing to the Riel rebellion, surveys were limited. Mr. William Ogilvie was engaged in making a survey of the railway line in British Columbia, to be used as a base for the future subdivision of surveys at points along the line. In March, Mr. Deville, then chief inspector of surveys, was appointed surveyor general, which position he is faithfully, conscientiously and intelligently occupying to this day. Mr. W. F. King was promoted to chief inspector of surveys.

In 1889, iron posts of a larger diameter were substituted at section corners, and the markings cut on the bars with cold chisels, a vast improvement on the original method of marking.

In 1890, Mr. King became chief astronomer of the department, and in May, 1893, Mr. J. S. Dennis became chief inspector of surveys.

In 1891, the Immigration Department was transferred from the Department of Agriculture to the Department of the Interior.

In 1892, Mr. W. F. King, D.T.S., was appointed international boundary commissioner, and in February of the same year, the Board of Examiners for Dominion Land Surveyors at Ottawa, passed the following resolution:—

"That this board, after due consideration, have come to the opinion that examinations for provincial land surveyors in Ontario and Manitoba are not sufficiently similar to those prescribed by the Dominion Lands Act, for Dominion land surveyors to entitle provincial land surveyors of those provinces to the privileges of Clause 109, and the board is further of the opinion that it is desirable in the interests of a uniform standard, that no candidate should be granted a commission as Dominion land surveyor unless he has passed the full examination prescribed by the Dominion Lands Act."

"Surveyors of the province of Ontario and Quebec are accordingly required to fulfil now the same conditions as surveyors of Dominion lands, instead of as formerly, being admitted after examination in the system of survey only."

It may be of interest to note here, that all western provinces now have separate surveyors' associations, and in order to obtain a commission to practice as a surveyor in any of the provinces, it is necessary for a Dominion land surveyor to pass an examination in conformity with the laws of each province.

Space does not permit touching upon the following very important surveys which have been administered by the Department of the Interior:—

The triangulation survey in British Columbia, commenced in 1889, under the superintendence of Mr. W. H. Drewry, D.L.S.

The photo-surveying in British Columbia, commenced in 1886, under the superintendence of Mr. J. J. McArthur, D.L.S.

International boundary survey of the 141st meridian, under the superintendence of Mr. W. F. King, D.T.S., boundary commissioner, commenced in 1906.

The irrigation survey in Alberta, under the superintendence of Mr. S. J. Dennis, D.T.S., then chief inspector of surveys, commenced in 1894.

The perusal of the reports on the above mentioned surveys are most instructive and interesting, and can be readily found in the annual reports of the department.

In 1901, Mr. Wm. Pearce was appointed chief inspector of surveys, and upon request was superannuated in 1904. In this year also the office of the surveyor general was moved from its quarters on Wellington Street, to its present location on Metcalfe Street, but owing to the growing increase of the staff in recent years, it was necessary to move part of the staff to the Imperial Building on Queen Street.

The present numerical strength of the surveyor general's staff is about 140, which is an indication of the clerical work performed by this important branch of the department.

In the surveyor general's report of 1903 it was provided by the Dominion Lands Act that the township subdivision surveys of Dominion lands should be performed under contract at a certain rate per township, per mile or per acre fixed, from time to time, by the governor-in-council or by competitive tender, as the governor-in-council would from time to time direct. The rates fixed under the provisions of this clause, at the inception of the surveys of Dominion lands more than 30 years ago, were, per mile of line surveyed, $7 for bare prairie, $18 for solid woods, and $11 for woods alternating with prairie. These rates remained in force until 1901, although the cost of labor and supplies had advanced considerably. In May, 1901, the rates were increased to $7, $13 and $21 respectively, but the cost of labor and supplies having continued to advance, the increase proved inadequate. The situation was aggravated by a succession of wet seasons, which made survey operations slow and costly. Survey contractors made little or no profit, and showed great reluctance in accepting new contracts. It was deemed reasonable that the rates should be increased sufficiently to leave a fair margin of profit to the contractors, and at the same time that the classification be revised so that the remuneration should be more nearly proportional to the cost of the survey. After consultation with all the surveyors who were engaged recently on township surveys, and who are conversant with present conditions, a new classification and schedule of rates was prepared and approved by order-in-council of February 3rd, 1903. The remuneration for prairie work was not increased, but surveys in the woods were, in some cases, paid as high as $38 per mile. The classification was entirely new and somewhat complicated; it was to be expected that experience would show the necessity of amendments.

Manual of Survey.—The last edition of the manual of instructions to surveyors for the survey of Dominion lands was issued in 1892; it was a revision of the previous edition (1883) prepared, under instructions of the Deputy Minister, by the chief astronomer, Mr. W. F. King, and the chief inspector of surveys, Mr. J. S. Dennis. A new revision had become necessary to bring our methods in accordance with the best modern practice, and to provide for the changes made in the system of survey during the last eleven years. The revision was prepared by the surveyor general, and issued to surveyors before the beginning of the present season's operations. An important departure from the previous practice is that township plans, instead of being made by the surveyors as formerly, will now be plotted from their field notes by the office staff. The plans will thus be made uniform and accurate —they will be made in better style and will contain all the information necessary for the record of a land survey; there will also be less delay between the completion of the surveys and the issue of the plans. Throughout the manual, the governing idea is that the plan of a land survey must be a true representation of the survey as it exists on the ground, and not a conventional illustration of the survey which it had been the intention to make. For this and other purposes, new clauses and numerous amendments to old ones were inserted. The old tables have been re-arranged and a new one compiled for the determination of the azimuth by the observation of Polaris. This last table will, it is believed, prove a most useful one to township surveyors; by its means, they may, at any time, in a few minutes, and almost without calculation, ascertain the astronomical bearings of the lines of survey. A very complete index is provided to facilitate references, and a large number of speciman plans and illustrations add to the value of the book. It is confidently expected that this manual will be found a very great improvement upon previous editions.

Remuneration of Surveyors, 1908.—At the inception of the survey of Dominion lands, nearly forty years ago, Dominion land surveyors were paid five dollars per day. Shortly after, six dollars per day was allowed to surveyors of base lines. These rates remained in force until 1901, when they were increased to $6.50 and $7.50 respectively. The advance proved inadequate; in order to induce properly educated men to qualify as Dominion land surveyors, so that there should be no difficulty in securing the services of competent surveyors when they are wanted, a further increase of $8 and $10, respectively, was granted by order-in-council of March 30th, 1908. The increase, it will be observed, is for ordinary surveyors, 60 per cent. over the rate of forty years ago; for surveyors of base lines it is a little over 60 per cent. Considering the enhanced cost of everything, the increase does not appear too large. By the same order-in-council the salary of the inspectors of surveys was fixed at $9 per day in the field and $5 per day at office work.

In August, 1911, an order-in-council was passed authorizing the payment of $12.50 per day to surveyors engaged upon the survey of base lines and initial meridians.

Inspection of Surveys.—In the earlier prosecution of the surveys, inspection was confined to a visiting of the various parties in the field by the inspector to satisfy himself that they were really at work, and to judge by what he saw of their manner of doing it, whether the requirements of the contract were being duly complied with; but, unless he became aware of something to give him suspicion of error or neglect, no check measurements were made beyond that of an occasional rough testing of an angle, with a pocket sextant that could be carried about by a person travelling on horseback or on foot, and generally alone. This kind of inspection, though certainly

inexpensive, proved to be correspondingly ineffective. It became evident that the cost must be incurred of applying check measurements to portions, chosen unsystematically, of each contract in order thus to insure the obtaining average samples of the work. Inspection surveys were therefore established. At first this consisted of lines run at random diagonally through a contractor's township and closing on the surrounding block outline surveys, with the object of having a rigid check both on the contractor and on the work of the inspection survey itself. This method was, however, abandoned on account of the labor it entailed in the office in obtaining, from the data, comparison of the actual position of boundaries checked, with that which theoretically they would occupy, and also because that the inspecting surveyor could judge but from what he saw at points where his lines intersected those of the contract, what care had been taken in placing its monuments.

To make a thorough inspection of a survey, it would be necessary to remeasure all its lines; in fact, an exhaustive inspection means a duplicate survey. This forms a fundamental objection to survey by contract. It is impossible that any government officer can certify that the full value has been received by the public for the contract money paid, unless he has so executed or caused to be executed, a duplicate survey. The most, therefore, that is practicable, within reasonable limits of cost for inspection, is that tests should be applied here and there at hazard, throughout a contractor's work, and the inspecting officer report the resulting facts, together with a presumptive opinion based thereon, respecting the necessarily very much larger untested portion of the contract.

To obtain a contract, a surveyor makes written application to the department for the sub-division of a number of townships (these contracts are limited in size from 4 to 8 townships). Before his application is accepted, he is requested to make himself conversant with the nature of the country in which his contract is situated. If he asks, he is given all the information possible that the department has relative to the description of the country, i.e., means of access, transportation, nearest post-office, railway and express offices. It is therefore through no fault of the department if he accepts blindly a contract and does not take sufficient time to complete his work. Contractors in general would find it to their advantage if they paid more attention to entering on the contract forms the dates of commencement and completion of their work, as it would save both themselves and the department a lot of unnecessary correspondence, besides worrying their sureties for an extension of time, etc. I would like to suggest that when contractors have a knowledge that the country they are going to work in is interspersed with numerous muskegs and unusually wet, it would be more advantageous to them to leave their work until the ground freezes. Nearly all our survey work now is in timber, in which there are great areas of swamps and muskegs, and the survey work (except mounding), can be done cheaper and just as accurately in the winter as in summer.

Every surveyor has his own particular method of conducting a survey, it therefore would appear presumptious to offer suggestions. However, I take the liberty of telling younger members of the profession, who are commencing contract work, that it is unnecessary to purchase a lot of horses, they are expensive and not absolutely necessary. Before going into your contract, establish a cache as near your work as possible and engage teamsters, half-breeds preferably, to haul your supplies there, and no matter what happens thereafter, you will at least have sufficient supplies to keep things moving; men will not work on empty stomachs. Make provision for your mail service at least once a month, it is absolutely necessary that you keep the department informed of your movements and progress, many vexatious delays are apt to occur if you do not, and the department is the one to suffer least.

One thing to be impressed strongly upon contractors is the incorrect placing of ¼ section monuments on chords. The inspectors find this a very common error, after the chords have been cut out and chained, the contractor is apt to leave the offsetting of these monuments to the mounders, who in many cases (as experience has shown) are apt to be careless and offset, if at all, the wrong way, this makes a very bad showing in the bearings of the chords and the error appears worse than it really is.

At this juncture it should be in order and to the best interests of all concerned if we discuss a few of the most salient points in connection with contract work. The points that most frequently arise between the inspector and contractor, are the following: Opening of lines; blazing of lines; marking on posts; classification; mounds and pits, and traversing.

There are frequent complaints that some contractors do not open their lines widely enough. Personally I do not think it is the intention of the department to require the surveyor to open lines wide enough to drive a wagon through, or cut off all trees and brush to within six inches of the ground. On the other hand, it is certainly not the intention to have lines so narrow that the line of sight can barely pass the trees. There should be a mean, and my own opinion is that no tree should be left standing that is within, say a foot of the line on either side of the line of sight. Of course there are exceptional cases, when the contractor runs against a tree close to the line, that is about three feet in diameter. In such isolated cases, I do not think the inspector would worry the contractor very much if this tree was not cut down, but rabbit runs and lines of the "key-hole" variety should be condemned, and the bush and wind fall cut low enough so as to insure accurate chaining.

Blazing.—Clause 76 of the Manual, reads in part as follows: "All lines are to be further marked by blazed trees not more than 75 links apart, and are not to be omitted when there are trees more than two inches in diameter within 50 links from the line. If this is not done, a maximum penalty of $2 per mile may be applied, see Clause 314."

In my opinion, the blazing of trees two inches in diameter is rather absurd, after a tree of this size is blazed on three sides little of the tree remains, at all events so much blazing is apt to kill it, thus rendering it useless as a permanent mark. I think this clause should be amended to read 3 inches in diameter. I also think that trees blazed 50 links from the line is too far away, 25 links is quite sufficient for all practical purposes.

Markings on Posts.—These should always be distinct and cut well into the iron, and care taken not to mark on the crown or penalty side of the bar. The markings on the iron posts, in many cases, are but indifferently done and sufficient care not given to the driving of them into the ground. At witness corners, in addition to the distance of bearing from the true corner, the reverse side is to be marked with the section number only, and but one side of a quarter section post is marked. A quarter section corner falling in a lake or marsh not more than three

feet deep is marked by a wooden post, flattened on two sides and marked. The post must not be less than five inches in diameter and long enough to be driven three feet into the ground and to show six inches above the water (Clause 152). Where there is a witness mound and a wooden post for the same corner, in my opinion the witness corner in case of dispute should govern.

Penalties are sometimes exacted for not driving the bars deep enough in the ground. There are cases where it is impossible to drive the bars the required limit, in rocky country, hard frozen ground, gravel and sand or in gumbo, and if you attempt to drive them in the top breaks off. The inspector in such cases should use his judgment. Care should be taken that all posts are lined in correctly by the instrument, as upon their "exact location" depends the bearings of the lines, and precision of future surveys. In my opinion the square ends of the bars are not long enough, there is not sufficient room for marking large numbers. I have spoken to the surveyor general about this, and he has promised that the next issue will have longer flattened ends. Bars should be driven in plumb.

Classification.—Clauses 311 to 314 of the Manual describe in detail what is expected from the contractor.

As our subdivision surveys are now nearly all in bush country, interspersed with muskegs and marshes, it is therefore only in the openings, across water or marshes where there should be any doubt in the ratings. As all openings of half a chain are required to be recorded, it appears to me that there should be but little difference of opinion as to the nature of classification (Clause 316). The contractor is given the benefit of the doubt, as whenever he shows proof of actual cutting, no matter how small the scrub, he is paid 100% for his work. This also applies to park country, where he may only have to cut down a tree in every five or six chains. Where surveys are made in the winter and examined in the summer, or vice versa, there is apt to be a difference of opinion between the contractor and inspector, as the topographical features are somewhat different, especially is this noticeable across muskegs, lakes, etc., etc. There appears to me good reason for argument in this proposition, as the inspector's returns are apt to vary from the contractor's. If the work of the inspector and contractor is done at different seasons of the year, consequently the returns in ratings will not agree.

Mounds and Pits.—There is a standard for the dimensions of all mounds and pits in the Manual of Survey (Clauses 154 and 155). It is no trouble to build mounds or dig pits in accordance with the standard, when the ground permits, and under such circumstances there is no excuse if not properly made, and a rigid enforcement of the regulations should be enacted. On the other hand, it is almost impossible to comply with these regulations, such as building mounds and digging pits in swamps and muskegs, the composition of the soil is such that when the mounds have been made the standard size, they will not retain their formation for any length of time, but shrink to almost half their original size; the same applies to the pits. The contractor builds them in water and muck and the inspector frequently examines them in drier weather, when the water has evaporated and the mounds and pits have in consequence shrunken considerably since being constructed. In such cases it seems to me hardly fair to impose a serious deduction on the contractor, unless the inspector is thoroughly satisfied that the mounds and pits were carelessly constructed in the first place. In such cases the inspector should use his own discretion, and when submitting his report to the department, explain in full his reason for condemning or approving these mounds and pits; a little give and take on the part of the inspector is in my opinion most desirable. Personally I have never been in favor of mounds in scrubby country, as experience has shown that they serve as an incentive to cattle and wild animals to stamp down, and supply additional material for filling in the pits, and now-a-days most farmers keep a few cattle. In the wilder regions the cut lines are regular pack trails for the wild animals. I consider that mounds built of earth, sod, stones and other material, will last longer and retain their formation better than if built of earth alone. Stone mounds, when properly built, form a good permanent mark, and if the iron bar is bent at right angles about the centre and one-half of it placed under the mound, it will, unless wilfully removed, remain in position for many years. It occasionally occurs that contractors place the iron posts at the east and west corners of the mounds, and sometimes build mounds and pits square with the line, when they should be placed diagonally. These are small errors, but should not be overlooked.

Traversing.—Clause 105, states that a hub shall be planted firmly where the line intersects the bank of a lake or river which has to be traversed. Do all surveyors comply with this regulation?

Clause 137 states that along tidal waters, the line to be traversed is the high water mark at ordinary tides. For a lake or navigable river, and also where the Irrigation Act applies, for a river not navigable, the line to be traversed is the bank. The bank, be it understood as applicable to a lake or navigable stream, is the edge of the bed of the lake or stream, and the limit of the bank is the line where vegitation ceases, and the shore is the space between high and low water mark at ordinary tides. As the edge of a marsh is inadmissible as a boundary, and subject to change, it follows that an inspector when making a traverse, should select a well defined boundary of a lake or river so that upon comparison there will be less likelihood of a disagreement between the contractor and the inspector's returns. Lakes that are traversed in the summer and inspected in the winter cause some trouble, as shore lines in many cases are bound to vary under the changed climatic conditions. It is permissible to make traverses with the chain, stadia or micrometer, if by the latter, the closing error must not exceed one chain in one hundred and the distances measured must not exceed half a mile. Traverses of lakes, rivers and connecting traverses are paid for at the rate of $11 per mile, and the distance paid for is between fixed points in a straight line.

Observations.—Clause 111, states that in subdividing townships at least one astronomical observation for ascertaining the direction of the meridian is made in each township, but two or more are desirable, etc., etc. When the weather is not favorable for observing, work may be commenced with an assumed meridian, and if possible connected by angular measurement with a base line. The telescope now used is powerful enough to show stars of the second magnitude within a few hours from noon, and stars of the third magnitude in twilight when it is still clear enough to read the graduation. The observation should be taken in daylight whenever practicable. A complete observation under favorable conditions, gives a result correct within a few seconds. An observation for time should be taken either shortly before or after every azimuth observation.

COAL PRODUCTION IN BRITISH COLUMBIA.

The collieries of the province made in 1912 a gross production of 3,025,709 tons (2,240 pounds) of coal, an increase over the preceding year of 727,991 tons equivalent to an increase of 31.5 per cent., according to statistics contained in the annual report of the Minister of Mines by Wm. F. Robertson, provincial mineralogist for British Columbia.

While this comparison is true, it must in fairness be stated that the producton for 1911 was much below normal, due to the labor troubles in the East Kootenay coalfield, whereby the collieries of that district were closed for the last eight months of the year.

It might be better, therefore, to make comparison with the year 1910, in which the coal production was by far the greatest in the history of coal-mining in the province and during which the gross coal production was 3,139,235 tons, or only 113,526 tons greater than last year.

Had it not been for labor troubles in the mines of the Canadian Collieries, on Vancouver Island, during the latter part of 1912, whereby the company's output was reduced to a point 150,000 tons lower than the preceding year, there is little doubt but that 1912 would have been the record year to date, instead of occupying second place; but, with the exception noted, it is greatly in advance of any other year.

The greater part of this production is still mined by three companies—the Crow's Nest Pass Coal Company of East Kootenay, the Canadian Collieries and the Western Fuel Company, of Vancouver Island, which mined, collectively, 75 per cent. of the gross output, their respective production representing 31.5 per cent., 34.5 per cent. and 19 per cent. of such total.

Of the other collieries: In the Coast District, on Vancouver Island, the Pacific Coast Coal Mines, Limited, produced 151,589 tons and the Vancouver-Nanaimo Coal Company, 88,253 tons and in the Nicola Valley section of the district, the Nicola Valley Coal and Coke Company mined 142,973 tons, the Inland Coal and Coke Company 31,300 tons, the Princeton Coal and Land Company, 28,174 tons, the Diamond Vale Coal Company, 3,310 tons, while the United Empire Coal Company made a start, producing some 500 tons of coal.

In the East Kootenay District, in addition to the Crow's Nest Pass Coal Company, which produced 950,706 tons, the Hosmer Mines, Limited, produced 188,243 tons and the Corbin Coal and Coke Company, 122,263 tons. In addition to those companies actually shipping, several other companies have been installing plant and have approached the shipping stage.

The collieries of the Coast District, including the Nicola Valley field, are to be credited for 1912 with about 58.3 per cent. of the total coal output.

The gross output of the collieries for the past year was, as already stated, 3,025,709 tons, in addition to which some 17,809 tons of coal was taken from stock, making the gross amount of coal distributed 3,043,518 tons. Of this gross amount, there was sold for consumption in Canada, 1,263,427 tons; sold for consumption in the United States, 858,981 tons; while 108,157 tons was exported to other countries, making the total coal sales for the year 2,230,565 tons of 2,240 pounds.

In addition to the coal sold, there was used in the manufacture of coke 396,905 tons, all in the East Kootenay field; and used under companies' boilers, etc., 240,304 tons; while 175,744 tons was lost in washing and screening.

There was no coke made last year in the Coast District, although some 4,266 tons was sold from stock, the total coke production having been made by the Crow's Nest Pass Coal Company, and Hosmer Mines, Limited, in the East Kootenay field, where from 306,005 tons of coal, 264,333 tons of coke was manufactured, of which 91 tons was used under the companies' boilers.

WATER POWERS IN NEW QUEBEC.

In extracts from reports published in bulletin form by the Department of Colonization, Mines and Fisheries on the district of Ungava, recently added to the Province of Quebec under the name of the territory of New Quebec, a vast amount of information is obtainable concerning this addition and that respecting its water powers is most interesting.

The interior of Ungava or New Quebec is a huge plateau which rises somewhat abruptly within a few miles of the coast line to a height of 1,500 to 2,500 feet. The various streams, therefore, afford numerous water-powers, more especially where they leave the interior plateau to flow through the strip of lowlands, a few miles wide immediately adjoining the coast. For instance, on Great Whale River, within 20 miles of the mouth, there are three falls 150 feet, 230 feet and 65 feet respectively. On the South branch of this same river, a few miles from its mouth, a fall of the river gives 136 feet. Nastapoka Falls near the coast has falls 170 feet. Near Richmond Gulf, the Wyachuan River falls give a head of 315 feet. A remarkable case of very high waterfalls in the interior is that of the Hamilton River. The Grand Falls of this river are situated some 300 miles from Rigolet. These falls were first viewed by a white man, John McLean, in 1839. McLean was in charge of the Hudson's Bay Company's post at Fort Chimo and crossed overland from that post to Hamilton Inlet.

The falls themselves have a sheer drop of 302 feet and Low estimated their discharge at 50,000 cubic feet per second. For twelve miles above the falls, the river rises rapidly, so that in the distance the difference of level, including the falls proper, is 760 feet. Adopting the discharge estimated by Low, these figures would give approximately 1,500,000 H.P., for the falls proper and 3,660,000 H.P. for the twelve miles of falls of the river. However, Dr. Low only saw the river during a period of high water and the above figures are probably much too high. In the data compiled by the Commission of Conservation and published in the "Report on Water-Powers in Canada," the possibilities of Grand Falls are based on a low-water drainage of 0.4 c.f. per second per square mile of drainage area, which is the quantity generally adopted under the climatic conditions of the country. Under these conditions, the estimated H.P. of the falls would be 120,000 and of the total fall for a distance of twelve miles 300,000.

A factory in Grenoble, France, utilizes the water of a reservoir situated in the mountains at a height of 200 yards. The water reaches the factory through a vertical tube of the same length, with a diameter of considerably less than an inch, the jet being used to move a turbine. Experiments have shown that the strongest men cannot cut the jet with the best-tempered sword; and in some instances the blade has been broken into fragments without deflecting a drop of water, and with as much violence as a pane of glass may be shattered by a blow from an iron bar. It has been calculated that a jet of water a small fraction of an inch in thickness, moving with sufficient velocity, could not be cut by a rifle bullet.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

REPORTS FROM MUNICIPAL ENGINEERS.

There is a great tendency among Canadian municipal engineers to evade written reports where possible. They surpass engineers of other countries in this respect, despite the fact that municipal engineering is comparatively young in Canada and requires as much benefit from reports of accomplished work as can be derived, if it is to hold its own with respect to the country's demands.

The value to one municipality of how work is progressing in others, what methods are being employed to advantage, and where warning notes should be sounded against unscientific or untried tactics, is obvious, and to the municipal engineer falls the duty of supplying his corporation with exact, concise and complete data, in order that the information may be of use, not only to itself but to sister municipalities.

But it is the value of these reports to the engineer himself that we wish to emphasize. So long recognized by engineering and business institutions, many of whose clerical compilations are nothing short of stupenduous, the value of records to him is as his confidence in future success. There are numerous occasions when reference to past work is needed at a moment's notice, and to come into contact with the advantages of written reports, one needs but to experience one or more embarrassments ensuing from the fallacy of attempting to recall the wording of previous oral reports, owing to the wanton traits of memory. If alone for the purpose of having an exact record of all his reports of progress, proposals, opinions, etc., to committees and to council, so that when desired, immediate and exact repetitions of statements made perhaps months before, may be presented, the engineer will find in it a safeguard to his professional standing in the community.

The exhortation applies more to the municipal engineer than to those of other branches of the profession owing to the wider and more diversified knowledge of engineering which he must necessarily possess. As his success generally depends upon his up-to-date knowledge of hydraulics, sanitation, surveying, railways, roads and pavements, electricity, structural work, etc., etc., his calling does not admit of traditional, rule-of-thumb, or unbusinesslike methods in any phase, and his brain will work up closer to the knee of its efficiency curve if it is not hampered by a continual trusting, or mistrusting, of memory. Finally, a municipal engineer's report should contain all that it is desired to express; it should be complete in itself, not requiring to be supplemented by oral explanations. It should be clear to avoid misconception or liability to distortion, and should be clothed in language understandable by men not fully conversant with engineering terms.

STRENGTH OF CONCRETE, WET vs. DRY.

Concrete has developed into a prominent essential of construction. Knowledge of the percentage range of water used in the making of it does not appear to have ever been apace with its widening scope of usefulness. Experiments on the relative strength of concrete having different degrees of plasticity have been comparatively few. There seems, nevertheless, to be a sufficient variation in strength between what is ordinarily known as wet concrete and dry concrete to endorse a more thorough investigation of it than has yet been carried on. The correct proportion of the other ingredients, and quality of

material, appear to have been receiving the bulk of the attention which has been given to the mixing of concrete in late years.

Some experiments, carried on nearly fifteen years ago, and claiming to be the first on the problem, brought out the advantages of working a wet mixture over a dry or moderately dry one, simultaneously stating that a moderate excess of water was in no way injurious to strength. Another report, the outcome of experiments by Mr. Irving Hiltz, of the Chicago, Milwaukee and St. Paul Railway, stated that it was impossible to get a compact concrete without using what might be theoretically termed an excess of water, while others claimed that a moderate use of water, tending, if anything, toward excess, was necessary for the strongest concrete.

Then, in 1903, Mr. J. W. Sussex, of the University of Illinois, arrived at a few conclusions that were a little less indefinite. His experiments were quite elaborate, as experiments with concrete went at that time, and from them he deduced the conclusion that dry concrete should never be used at all; that medium concrete might be used where immediate strength is desired, but that a wet mixture would produce concrete stronger and cheaper than either dry or medium, at any age beyond three months.

It will be interesting for engineers conversant with the more recent reports of special committees of our technical societies and of engineering testing laboratories to compare them with the conclusions of earlier experimenters as mentioned above.

EDITORIAL COMMENT.

The third annual congress of the Canadian Public Health Association will be held in Regina on Thursday, Friday and Saturday, September 18, 19 and 20, instead of 16, 17 and 18, as previously announced. The programme of papers promises to be an exceptionally attractive one, and the Provincial Government and the city of Regina are co-operating in plans for the entertainment of the delegates.

* * * *

Canada's side of the boundary dispute arising from the proposal of the Michigan-Lake Superior Power Company, referred to editorially in July 10th issue of *The Canadian Engineer*, is being prepared by Mr. Chas. S. MacInnes, K.C., of Toronto. The lease, as proposed, occasions a diversion by dam of the St. Mary's River flow at Sault Ste. Marie, Ont., and has aroused a good deal of discussion.

* * * *

Owing to the number of requests for copies of Mr. J. M. M. Greig's "Sewer Discharge Diagram," reprints of which were made from the article appearing in June 5th issue of *The Canadian Engineer* for distribution to interested engineers, our supply was soon exhausted, and the continued accumulation of requests has occasioned the printing of another edition. These are being mailed to readers upon request.

The mineral production of Alaska for 1912 amounted to $21,850,000, of which $16,650,000 was in gold, $4,630,000 in copper, $300,000 in silver and $260,000 in tin, marble, gypsum, coal and petroleum.

DRAINAGE AS AFFECTING HIGHWAY TRAFFIC.

THE increasing use of highways by heavy traffic has brought forcibly before those who have charge of them the weakening effect of water which is allowed to remain on the surface, in the subsoil, or in close proximity to it. Mr. W. Gregory, who has had over twenty years' experience in English road construction and maintenance, writing in Contractors' Record and Municipal Engineering, London, covers many important points that will be of interest to highway engineers who have to contend with the difficult drainage of stretches of road where surface water is not disposed to depart without a struggle.

To a casual observer, it might seem to be efficient drainage to conduct ordinary surface water by cross channels to back ditches, and away by the natural outfalls.

There are, however, miles of roads which, by reason of their cross section and situation, are practically waterlogged, as, for instance, where passing between high banks, with surrounding land several feet higher than the road surface, while the roads are so narrow that two vehicles can barely pass at walking pace; it will be obvious that in such cases ditches at sides are sources of more or less danger, while their absence produces mudholes in wet, and ice in frosty weather.

Even where there is sufficient width of surface and greensward to construct back ditches, there are not always sufficient to drain a road effectively. Roads passing over clay lands, in a wet season, are, regarding their subsoils, in a tremulous condition.

The experience of the writer, for some years, has been with roads resting on clay, chalk, or a combination of both, where this state of things has given rise to much difficulty.

The increased use of mechanical means for agricultural work has produced serious effects on roads only made to carry ordinary light vehicular and farm traffic; the passage along roads of heavy steam ploughs, usually in couples, and with vans and tackle totalling in weight anything from 40 to 60 tons, traction engines drawing laden trucks, threshing equipment, heavy motor lorries, etc., has produced such an alteration in the shape of the road crust that it was puzzling at first to know how best effectively to deal with it.

Some years since the writer decided to lay deep side drains in these weak roads, which should act in a threefold capacity, as surface water drains, subsoil drains, and abutments for the thrust of heavy vehicles. In many instances the passage of heavy engines had squeezed the ordinary side ditches up higher than the road surface, rendering them useless, and the constant attention, digging out and levelling was of little avail in draining the road.

These side drains were dug to at least 3 feet in depth, the outfall being in some ditch or natural watercourse, and where, owing to the variations in levels, the drain came near to the surface, iron pipes were used until a minimum cover of 2 ft. 6 in. was obtained, when glazed earthenware socket pipes of 6 in. diameter were used, these being laid with open joints and the trench carefully filled with large lump hardcore, or boulders, and finished near the surface with smaller stones, down to 1¼ in. size.

At intervals, depending on local circumstances, 9-in. brick catchpits, 24 in. by 18 in. by 3 ft. 6 in. depth, were

constructed, with ordinary cast iron, hinged gulley gratings as covers.

Where these have been laid the effect on the roads has been most marked, the sides being firm, and the aerating effect on the subsoil has diminished the rolling movement of the clay to a minimum, although the engine traffic has enormously increased.

There has been considerable opposition by local people, and the work has been referred to as useless and a waste of ratepayers' money, the prevalent idea being that what was good enough for the former generations is good enough for the present day; and the instilling of scientific knowledge into the minds of such ratepayers is not a pleasant occupation, but the sooner they realize the benefits to the roads from these works the more likely are the highway surveyors and engineers to be able to improve roads to meet the requirements of modern traffic.

One instance of the effectiveness of these drains will illustrate the whole. During a dry portion of the year, the outfall of the longest drain (half a mile) was gauged, and found on different occasions to discharge 10,000 gallons per 24 hours; previously the road absorbed or carried this water, forming a slough in damp weather and being almost impassable in frost.

The cost in the district under reference would be much higher, no doubt, than in many other parts, as there is no suitable local material (in fact, no local road metal at all), and the distance from railway stations varies from 3 to 7 miles.

The work, with the exception of the catchpits, is done by the ordinary roadmen, and the cost (including pipes, metal, labor, carting, brickwork, etc.) does not exceed $1.85 per lineal yard, and in some cases less.

The extended use of by-roads by heavy traffic calls for a much higher standard of surface than formerly, and the above method, in the writer's opinion, will do much towards bringing this desirable state to pass, and enabling a road with a thin crust of metal to carry a greater amount of heavy traffic than it otherwise could, with less damage to the surface.

In many cases, the effect of the enormous weights on these roads appears to be the alteration of minor springs in the subsoil, and forcible closing of some of the capillary passages of water, resulting in springs bursting through the crust in places not previously known.

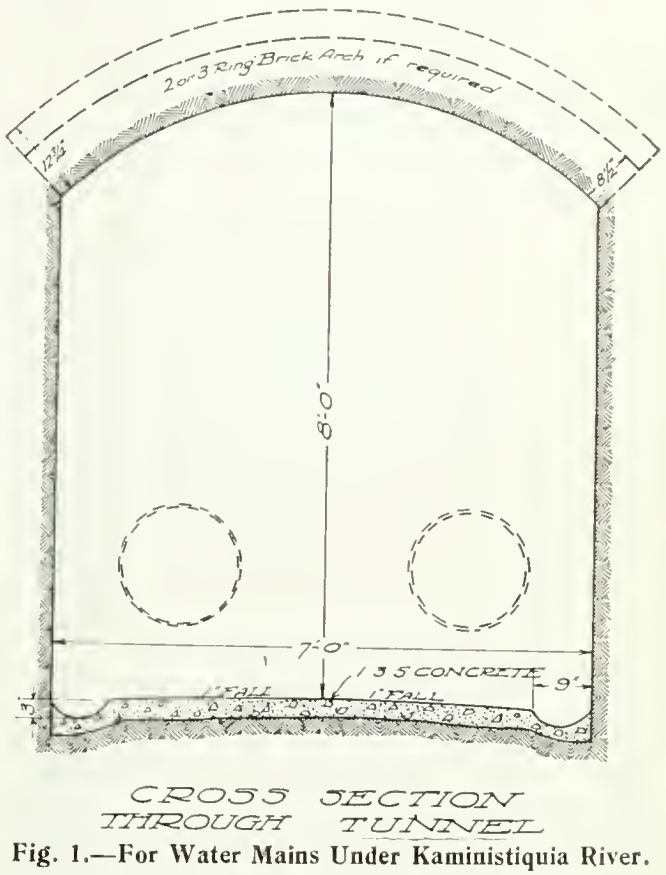
An instance of this occurred some years since, where, owing to months of wet weather, the high, clayey fields adjoining a road (in a cutting) presumably became surcharged with water, which burst out on the face of a hill in the centre of the road, the whole surface suddenly giving way as a vertical quagmire, to a depth of 3 or 4 feet.

The immediate remedy was to start lower down the hill with two trenches at sides of road, and work upwards, gradually increasing the depth until level with the bottom of the burst and joining the two trenches in the centre of same. Pipes were then laid from centre along each trench, and the water conducted so as to emerge at sides further down the hill, the trenches and centre being filled in with brick rubble, etc., that could be obtained, and, when settled, the surface coated with metal.

Similar cases, but in a minor degree, occur on trunk roads which have been tarred, one helping cause, no doubt, being the prevention of ventilation by the tarred surface, and the retention of the water until the pressure of same, or the heavy traffic, causes the surface to give way.

RIVER CROSSINGS FOR WATER MAINS AT FORT WILLIAM.

THE city of Fort William obtains its water supply from Loch Lomond, a lake located about six miles from the city, about 10 square miles in area, draining a watershed of about 30 square miles; at an elevation of 332 feet above Lake Superior. The system at present laid out consists of tapping this source with a 36-inch diameter steel intake pipe, which, at normal lake level, has a capable discharge of 32,000,000 Imperial gallons per day into a gate chamber. From the gate chamber to a fore bay a tunnel is constructed about 5,000 feet in length, 5 ft. by 4 ft. in size. This tunnel is so laid that it serves simply as an arm of the lake, the water level in the fore bay being the same as the lake level. The capable discharge of the tunnel approximates 54,000,000 gallons per day. From the fore bay a gravity



CROSS SECTION THROUGH TUNNEL

Fig. 1.—For Water Mains Under Kaministiquia River.

18-inch diameter cast-iron pipe is laid for a distance of 3,356 yards, discharging into a reservoir which provides the static head to the city supply. With normal lake level and the reservoir standing three-quarters full (with 15 feet depth of water) the discharge of this pipe is about 3,657,000 Imperial gallons per day, which can be increased up to 4,198,800 gallons per day at the expense of lowering the water in the reservoir to zero, with consequent loss of static head to the city supply.

The 18-inch pressure main crosses the Kaministiquia River at a point south of and in line with Syndicate Avenue. The pipe is laid in duplicate on concrete slabs practically in the river bed, and is provided with controlling valves at each side of the river.

Desiring to increase its water supply, the city contemplates a duplication of pipe lines between the fore bay and the city and the addition of a 24-inch pipe line, pro-

viding then an available supply of over 11,000,000 gallons per day.

The proposed extensions necessitate the abandonment of the present Kaministiquia River crossing and the provision of tunnel crossings about 650 feet in length under the Mission and McKellar Rivers, while the Kaministiquia River will be crossed in another spot by a tunnel some 1,285 feet in length, and with cross-section and dimensions as shown in Fig. 1. The design of this shaft and tunnel system presents some very interesting

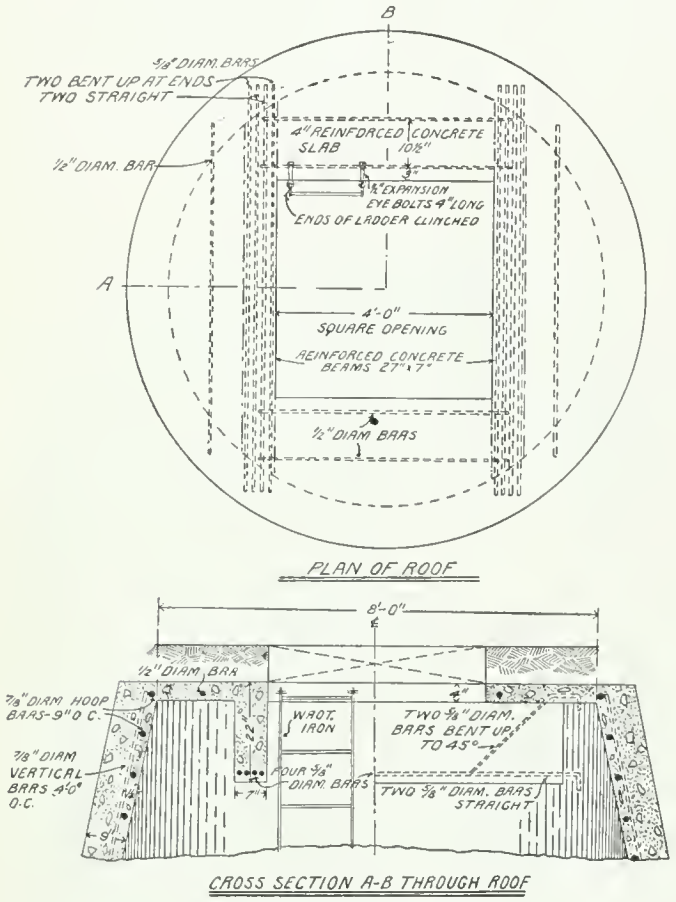


Fig. 2.—Details of Shaft on Each End of River Tunnel.

features, particularly with respect to the shafts. Those at the Kaministiquia River crossing are typical, and, being the largest, they are chosen for this description. Figs. 1 and 2 show details of roof and platform respectively.

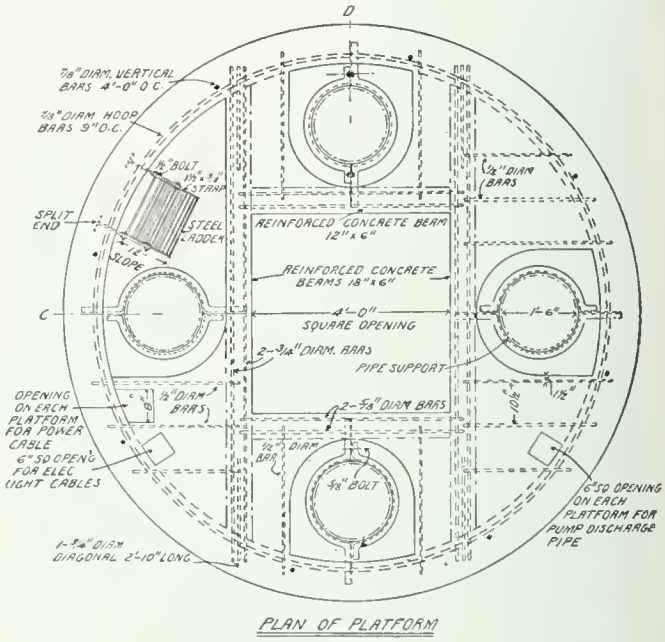
The typical shaft is lined with reinforced concrete and is provided with reinforced concrete platforms, at normal intervals of 20 ft. to serve as landings for the ladders and to provide support for the pipe lines. At the Kaministiquia crossing there will be two reinforced concrete lined rock cut shafts each 10 ft. in diameter. They are 121 ft. 9 ins. and 116 ft. deep, traversing sand, blue clay, dyke, broken rock and Hudson shale. The concrete shaft lining is carried into the shale for at least 6 ft. Below this point the shaft is rock cut and a lining is not necessary. The tunnel lies wholly in the Hudson shale.

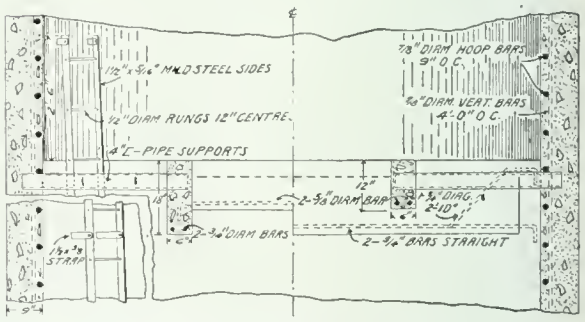
The reinforced lining is a 1 :2 :4 concrete, 9 ins. thick. The vertical reinforcement consists of ⅞-in. round rods spaced 4 ft. apart The horizontal rods are also ⅞ in. round, and are spaced 9 ins. on centre.

The sinking of these concrete linings provides an interesting problem. If the choice of the contractor is to build them at or near the ground level, and then sink them by gravity, steel shoes will be required to form the footing, and the concrete will require at least 48 hours in which to properly set before lowering.

The use of the lubricant between the lining and excavation walls will likely be taken advantage of to facilitate sinking.

For this form of construction care must always be exercised to excavate to a true circle of not more that ½ in. larger diameter than the outside of the concrete linings. If deemed necessary the linings should be slowly and evenly lowered by means of screw jacks. For this form of construction it is also specified that three times the number of vertical reinforcing rods shown in the accompanying illustrations be used. When the shoe reaches





½" x ⅝" M.S. STEEL SIDES

CROSS SECTION C-D THROUGH PLATFORM

Fig. 3.—Details of Shaft Platform.

the rock an excavation will be made into the rock to a depth of 1 ft., so that the shoe will have an even bearing. The cavity left will be built up with brickwork and grouted in. Air and grout pipes at 2-ft. intervals will be provided for this purpose.

Only steel forms will be used on the concrete shaft linings. These forms will be well braced and stiffened to prevent deflection or twisting. Variations in the line and level exceeding ¼ in. will not be permitted in placing the forms

In case the reinforced concrete platforms are built after the shaft lining is completed, holes will be drilled for reinforcing bars, and cuts at least 1½ ins. deep will

be made in the lining to receive the ends of the beams and slabs.

Where shale or loose rock is encountered in the roof of the tunnels this material will be removed and replaced with a brick arch. Permanent sumps and segmented drains will be cut in the rock at the bottoms of the shafts and along the floor of the tunnel. At intervals of 12 ft. along the tunnel floor, hardwood blocks 3 ft. long by 8 ins. wide by 3 ins. deep will be placed for pipe supports.

The work was designed by Mr. T. Aird Murray, consulting engineer, and will be carried out under the direction of Mr. R. R. Knight, city engineer, of Fort William.

A HANDY PLUMB BOB HOLDER.

The carrying of the plumb bob from station to station, or to and from the line, has always been a source of annoyance to the transit-man. It will persist in punching holes in pockets and getting lost.

A device is described by F. H. Kitto, D.L.S., in the latest annual report of the Association of Dominion Land Surveyors, that will serve to overcome a great deal of annoyance from this source. It consists of a simple attachment on one leg of the tripod, for holding the plumb bob when not in use, and forms, in fact, a neat permanent receptacle for it, so that it is always with the tripod when required.

The attachment is briefly described as follows: The point of the plumb bob is safely disposed of by dropping it into a hole ¼ inch in diameter bored to a depth of ½ inch in the centre of the wood cross-piece of the tripod leg. The neck of the plumb bob rests in a strip of brass extending across the split of the tripod leg, and fastened at each end by two half-inch screws. This brass strip is bent to a curve at the centre so as to fit the neck of the tripod. The outer strip is also of brass and hinged at one end on a round-headed inch screw, which passes through the inner plate and screws firmly into the wood. The other end hooks over a pin which is fitted as a clamp screw, so that by a slight turn of the mill-headed thumb nut the plate cannot come unfastened and allow the plumb bob to drop out. This screw extends through the wood of the leg and tightens in a nut, which is fitted by two ⅜ inch screws to the inner side of the leg. The inner plate is bent in such a way that the neck of the plumb bob does not exactly fill it, but is gripped on either side. This is to allow for string which is generally wrapped around the neck. As the plate will spring according to the thickness of string, the plumb bob is always held firmly.

This is a very simple contrivance, easily made and easily fitted to the tripod; and a great deal of satisfaction may be received from this little arrangement. There is no place more convenient for the plumb bob when carrying the transit, or when the transit is in camp, on transport, or in the office. It cannot be lost and it cannot be forgotten.

A calculation has been made of the time that elapses before a drop of water evaporated on the surface returns to the ocean. The total volume of water brought annually to the sea is 1/3460 of the total contents of the ocean. A particle of water before evaporation has stayed in the ocean on an average 3,460 years. Once evaporated, the drop becomes condensed in about ten days and is then speedily drawn back to its ancient home.

MUNICIPAL WATER SOFTENING

By Geo. A. Johnson.

HARD waters—those containing high quantities of lime and magnesia in a dissolved state—are less desirable for domestic and industrial use than soft waters. Hard water produces scale in boilers, wastes coal, and shortens the life of the boiler. It is ill-suited to the needs of many industries, particularly those in which chemicals are used, such as paper mills. Hard water wastes soap in the laundry and frequently makes necessary the use of washing soda or other compounds which have an injurious effect on some fabrics. It almost always affects the skin unpleasantly, and is more or less undesirable and uneconomical in various ways for general household use. A careful treatment of the subject forms a part of a paper by Mr. Johnson entitled "The Purification of Public Water Supplies," and published by the United States Geological Survey. Important features of the subject of water softening for domestic purposes are therein discussed.

Waters which have a total hardness of over 50 parts per million (3 grains per gallon) are usually classed among the hard waters. Such waters as these are found in scores of cities in this country, particularly in regions where limestone deposits predominate. To illustrate this point a few examples are given of some of the hardest water supplies of the United States. This is, of course, a very incomplete list, and could be added to almost indefinitely. The figures given for total hardness are necessarily approximate, for the hardness of a water naturally fluctuates widely during the year, becoming greater during the months of low stream flow and least during high-water periods.

Approximate Total Hardness of the Raw-water Supplies of Some U.S. Cities.

	Parts per Million.		Parts per Million.

Water softening is not widely practiced in America except by private industries. Among the cities where the public supply is softened may be mentioned Freeport, Ill., Oberlin, Ohio, St. Louis, Mo., McKeesport, Pa., New Orleans, La., and Columbus, Ohio, the municipal water-softening plant at Columbus, first placed in operation in the fall of 1908, being the largest and the most complete. For complete details of the chemistry of the water-softening problem at Columbus, the reader is referred to an article by A. E. Kimberly, published in the supplement to the Journal of Infectious Diseases, May, 1909.

Dissolved Mineral Constituents.—In problems of water softening, the most important features requiring thorough and reliable data are particularly the nature and the relative amount of the dissolved mineral constituents to the presence of which the water owes its hardness. Such data indicate, in large measure, the treatment of the water best adapted to its softening. With rare ex-

ceptions the hardness of water is due to the presence of calcium and magnesium radicles.

There are two kinds of hardness, temporary and permanent. Waters in which carbonate or bicarbonate radicles are equal or greater in reacting value than the calcium and magnesium may be almost completely softened by boiling and their hardness is known as temporary. Waters in which carbonate and bicarbonate radicles are less in reacting value than the calcium and magnesium can not be effectively softened by boiling. The removal of all the calcium and magnesium from such water can be effected only by the addition of chemicals that will cause the formation of insoluble calcium and magnesium compounds. Hardness corresponding to the excess in reacting value of calcium and magnesium over carbonate and bicarbonate radicles is termed permanent.

Lime and Soda Ash as Softening Agents.—The process of softening water consists primarily in removing from it the calcium and magnesium radicles. This is accomplished with lime and soda ash by the formation of insoluble compounds of these radicles, but these chemicals also react with other substances in the water. The lime is introduced as calcium hydroxide and the soda ash as sodium carbonate. The effects are:

(1) Hydrogen (acidity) is neutralized, forming water; (2) carbon dioxide is changed to carbonate radicle and water; (3) bicarbonate is changed to carbonate radicle and water; (4) iron, aluminum, and magnesium form their insoluble hydroxides and fall as precipitates; (5) calcium present in the water and added as lime is precipitated as calcium carbonate; (6) the sodium of the added soda ash remains in solution in the water.

From the foregoing it appears that lime must be added in quantity sufficient to provide hydroxyl (OH) to combine with the iron, aluminum, magnesium, bicarbonate, and hydrogen radicles, and carbon dioxide. Moreover, if the carbonate radicle in the water plus that formed by the change of the bicarbonate radicle and carbon dioxide is not sufficient to precipitate the calcium present in the water and added as lime, a larger quantity must be provided by the addition of soda ash in order that all the calcium may be precipitated. This latter consideration determines the amount of soda ash to be added. In terms of pounds of 90 per cent. (CoO) and 95 per cent. soda ash (Na_2CO_3) per 1,000 gallons of water, these statements may be expressed in the following formulas, in which the symbols represent the number of parts per million of the various radicles, respectively, found by analysis. The symbol "r" represents the "reaction coefficient." The indicated product represents reacting value in parts per million.

1. Lime required:

$$= 0.26\ (rFe + rAl + rMg + rH + rHCO_3 + 0.0454CO_2)$$
$$= 0.00931\ Fe + 0.0288Al + 0.0214Mg + 0.258H + 0.00426HCO_3 + 0.0118CO_2.$$

2. Soda ash required:

$$= 0.465\ (rFe + rAl + rCa + rMg + rH - rCO_3 - rHCO_3)$$
$$= 0.0167\ Fe + 0.0515Al + 0.0232Ca + 0.0382Mg + 0.462H - 0.0155CO_3 - 0.00763HCO_3.$$

In the latter formula a negative value indicates that the water has no permanent hardness and that the use of soda ash is unnecessary.

The formulas may usually be simplified for practical use by the omission of iron, aluminum, and hydrogen, for they are not often present in sufficient quantity to affect the results. Total incrustants in parts per million (as determined by the standard method of the American Public Health Association) multiplied by 0.0093 will be practically equal to the value of Formula 2.

Manufacture of Lime.—The raw material for the manufacture of lime is carbonate of lime, either as a natural limestone or in the form of the shells of mollusks. By subjecting the raw material to a temperature of 900° to 1,000° C., the carbonic acid is driven off and calcium oxide or quicklime is left.

There are two distinct types of furnace in use for the manufacture of lime, namely, periodic and continuous kilns. In the continuous system the kilns, once charged with alternate layers of limestone and fuel, are never allowed to cool down, resulting in great economy of heat. In this country more lime is perhaps burnt in kilns operated periodically. In this system the charged kiln, after the burning, is allowed to cool down, the lime is removed, and the kiln is recharged and reheated for the following run. In comparison with the continuous system, the periodic method of operation is uneconomical, owing to the losses involved in fuel and in time.

As the result of the burning a good limestone is broken into lumps; it suffers no change in volume, its weight and properties only being affected. The loss of weight during the decarbonization is about 50 per cent. Well-burnt and entirely satisfactory lime should be porous, nearly as hard as the original limestone, and should contain little, if any, magnesium and but inappreciable quantities of silica and iron. For softening water, economy and expediency demand that the highest grade of lime obtainable should be used. It is evident that for softening water the value of a given lime is dependent on the amount of available calcium oxide it contains. As lime is bought and sold on this basis for softening water, the chemical analysis should be the standard under all circumstances.

Manufacture of Soda Ash.—The manufacturing process of soda ash depends on the fact that bicarbonate of soda is insoluble in ammoniacal solutions of common salt. Common salt, ammonia gas, and carbonic acid gas constitute the raw materials. Strong brine saturated with ammonia is pumped to the top of carbonating towers and allowed to descend through iron baffle plates up through which a stream of carbonic acid is constantly flowing. Under these conditions bicarbonate of soda is formed and separates out, falling to the bottom of the tower, whence it is removed. The crude product is subsequently calcined, carbonic acid and water are driven off, and the pure normal carbonate of soda or soda ash is left.

Soda ash of a high degree of purity may be obtained in the market, and such soda ash alone should be used in all water-softening plants. The percentage of soda ash will vary from 95 to 98 per cent.

Cost.—The cost of high-grade lime and soda ash is subject to considerable fluctuation. Speaking generally, a high-grade lime, containing 90 per cent. available calcium oxide or more, may be obtained for about $4.50 a ton in bulk in carload lots. Soda ash, containing upward of 95 per cent. sodium carbonate, may be obtained in bags of 300 pounds each for about $20, or somewhat less, a ton in carload lots.

Preparation of Lime Solution.—It may be stated, practically without reservation, that it is advisable to use limewater for softening water. The reason for this is that limewater, being a true solution, is much more readily applied in uniform quantities than milk of lime. In water-softening plants which are operated on an intermittent basis it is possible to make use of milk of lime, owing to

the fact that the application of the desired amounts of chemical may be kept under strict control. In plants which are operated on a continuous basis it is obvious that the effect of errors relating to the faulty application of lime must in a great measure vary inversely with the amount of water to be treated, or, in other words, with the amount of chemical to be used.
